

# Filtering Images in the Spatial Domain

## Chapter 3b G&W

Ross Whitaker

(modified by Guido Gerig)

School of Computing

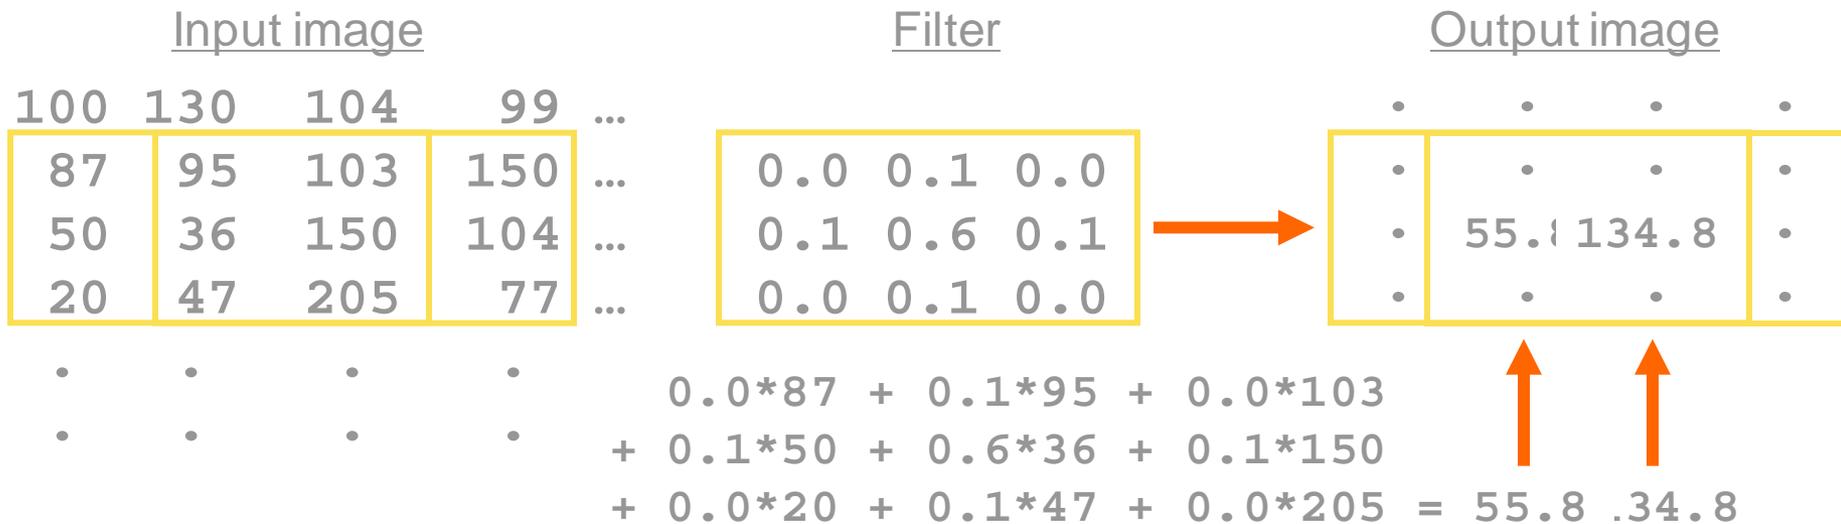

University of Utah

# Overview

- Correlation and convolution
- Linear filtering
  - Smoothing, kernels, models
  - Detection
  - Derivatives
- Nonlinear filtering
  - Median filtering
  - Bilateral filtering
  - Neighborhood statistics and nonlocal filtering

# Cross Correlation

- Operation on image neighborhood and small ...
  - “mask”, “filter”, “stencil”, “kernel”
- Linear operations within a moving window

# Cross Correlation

- **1D**  $g(x) = \sum_{s=-a}^a w(s) f(x + s)$

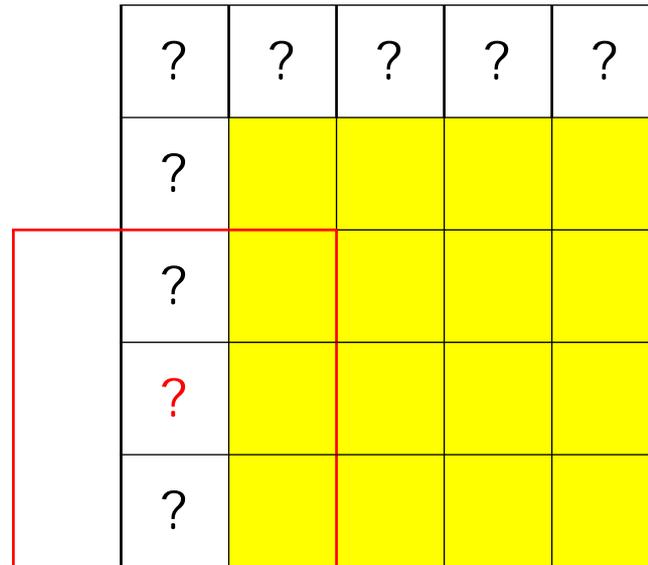

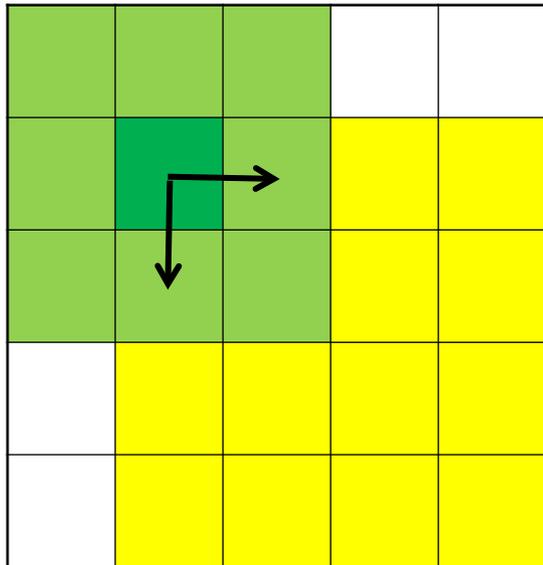

- **2D**  $g(x, y) = \sum_{s=-a}^a \sum_{t=-b}^b w(s, t) f(x + s, y + t)$

---

$$w(s, t) = \begin{array}{cccc} w(-a, -b) & \cdots & \cdots & w(a, -b) \\ \vdots & & & \vdots \\ & \cdots & w(0, 0) & \cdots \\ \vdots & & & \vdots \\ w(-a, b) & \cdots & \cdots & w(a, b) \end{array}$$

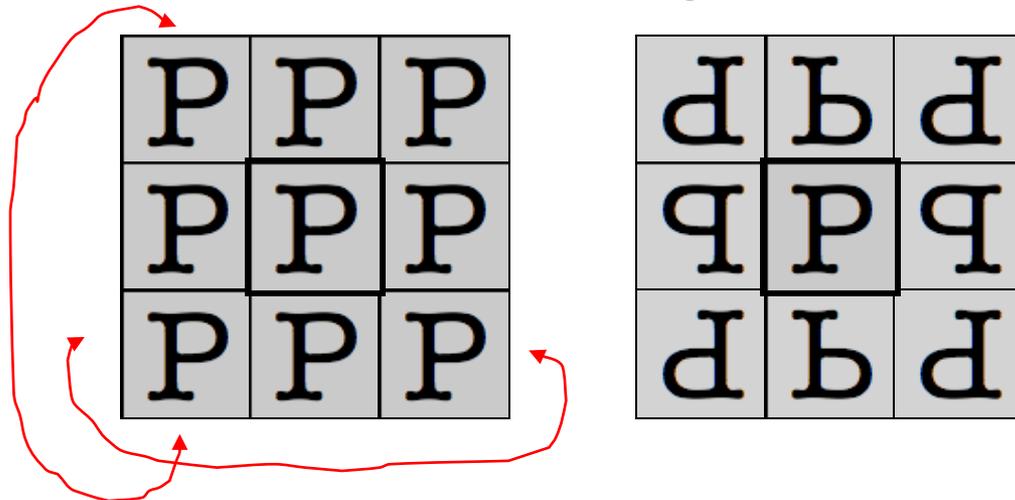

# Correlation: Technical Details

- How to filter boundary?

# Correlation: Technical Details

- **Boundary conditions**
  - Boundary not filtered (keep it 0)
  - Pad image with amount (a,b)
    - Constant value or repeat edge values
  - **Cyclical boundary conditions**
    - Wrap or mirroring

# Correlation: Technical Details

- **Boundaries**

- Can also modify kernel – no longer correlation

- **For analysis**

- Image domains infinite

- Data compact (goes to zero far away from origin)

$$g(x, y) = \sum_{s=-\infty}^{\infty} \sum_{t=-\infty}^{\infty} w(s, t) f(x + s, y + t)$$

# Correlation: Properties

- Shift invariant

$$g = w \circ f \quad g(x, y) = w(x, y) \circ f(x, y)$$

$$w(x, y) \circ f(x-x_0, y-y_0) = \sum_{s=-\infty}^{\infty} \sum_{t=-\infty}^{\infty} w(s, t) f(x-x_0+s, y-y_0+t) = g(x-x_0, y-y_0)$$

# Correlation: Properties

- **Shift invariant**

$$g = w \circ f \quad g(x, y) = w(x, y) \circ f(x, y)$$

$$w(x, y) \circ f(x-x_0, y-y_0) = \sum_{s=-\infty}^{\infty} \sum_{t=-\infty}^{\infty} w(s, t) f(x-x_0+s, y-y_0+t) = g(x-x_0, y-y_0)$$

- **Linear**  $w \circ (\alpha e + \beta f) = \alpha w \circ e + \beta w \circ f$

Compact notation

$$C_{wf} = w \circ f$$

# Filters: Considerations

- **Normalize**
  - Sums to one
  - Sums to zero (some cases, see later)
- **Symmetry**
  - Left, right, up, down
  - Rotational
- **Special case: auto correlation**

$$C_{ff} = f \circ f$$

# Examples 1

$$\begin{matrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{matrix}$$

$$\frac{1}{9} * \begin{matrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{matrix}$$

# Examples 1

$$\frac{1}{9} * \begin{matrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{matrix}$$

# Examples 2

$$\frac{1}{9} * \begin{matrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{matrix}$$

$$\frac{1}{25} * \begin{matrix} 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 \end{matrix}$$

# Smoothing and Noise

Noisy image

5x5 box filter

# Other Filters

- **Disk**
  - Circularly symmetric, jagged in discrete case
- **Gaussians**
  - Circularly symmetric, smooth for large enough stdev
  - Must normalize in order to sum to one
- **Derivatives – discrete/finite differences**
  - Operators

# Gaussian Kernel

```
 $\sigma = 1; \text{Plot}\left[\frac{1}{\sqrt{2\pi\sigma^2}} E^{-\frac{x^2}{2\sigma^2}}, \{x, -4, 4\}, \text{ImageSize} \rightarrow$ 
```

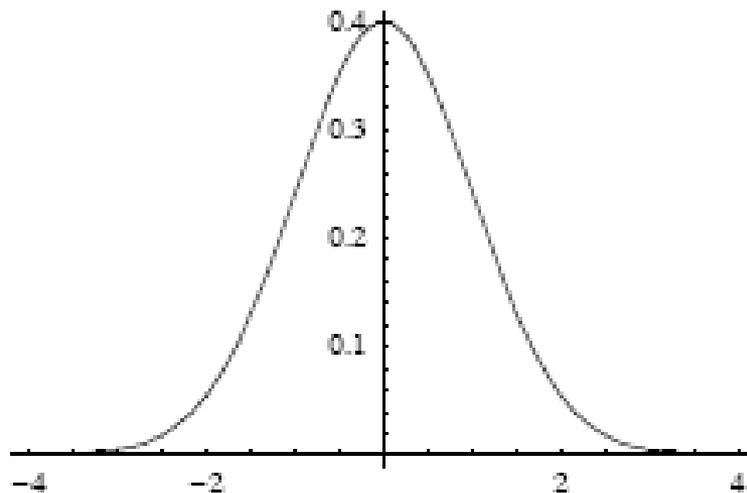

Figure 2.1 The Gaussian kernel with unit standard deviation in 1D.

# Gaussian Kernel

$$G_{1D}(x; \sigma) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{x^2}{2\sigma^2}}, \quad G_{2D}(x, y; \sigma) = \frac{1}{2\pi\sigma^2} e^{-\frac{x^2+y^2}{2\sigma^2}}, \quad G_{ND}(\vec{x}; \sigma) = \frac{1}{(\sqrt{2\pi}\sigma)^N} e^{-\frac{|\vec{x}|^2}{2\sigma^2}}$$

Normalization to 1.0

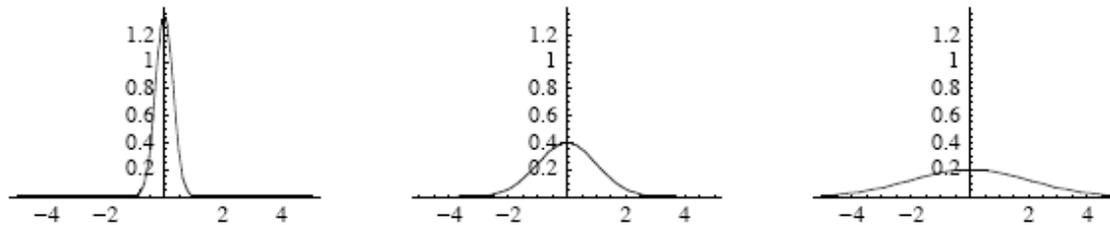

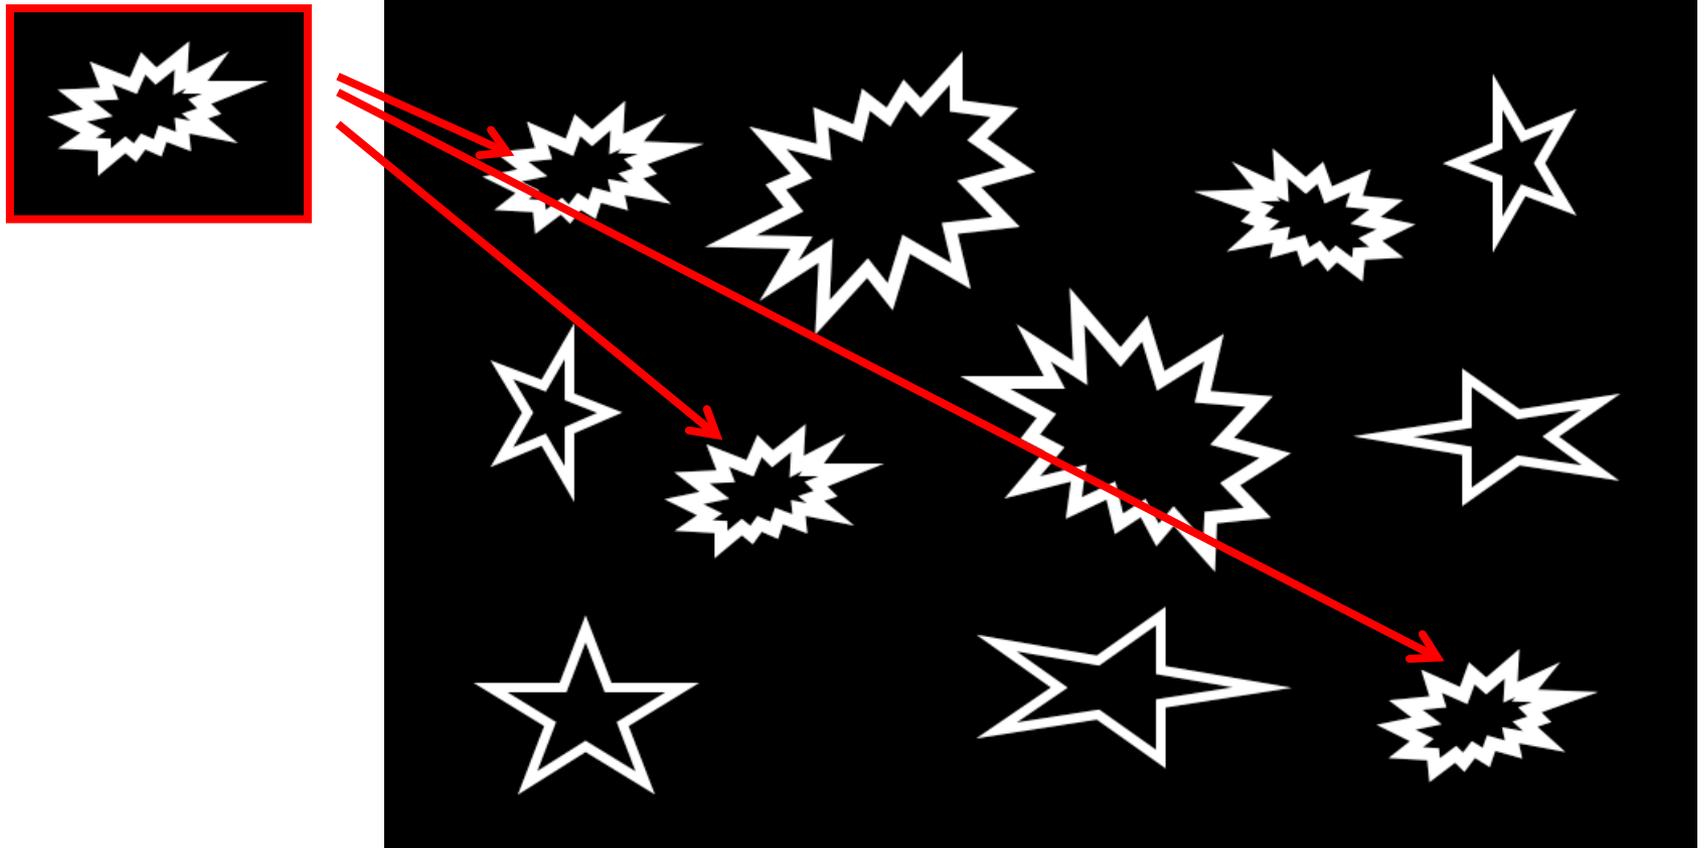

Figure 3.2 The Gaussian function at scales  $\sigma = .3$ ,  $\sigma = 1$  and  $\sigma = 2$ . The kernel is normalized, so the total area under the curve is always unity.

# Pattern Matching

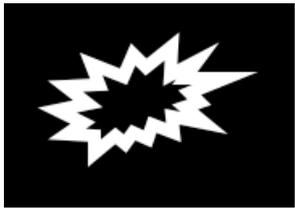

# Pattern Matching/Detection

- The optimal (highest) response from a filter is the autocorrelation evaluated at position zero

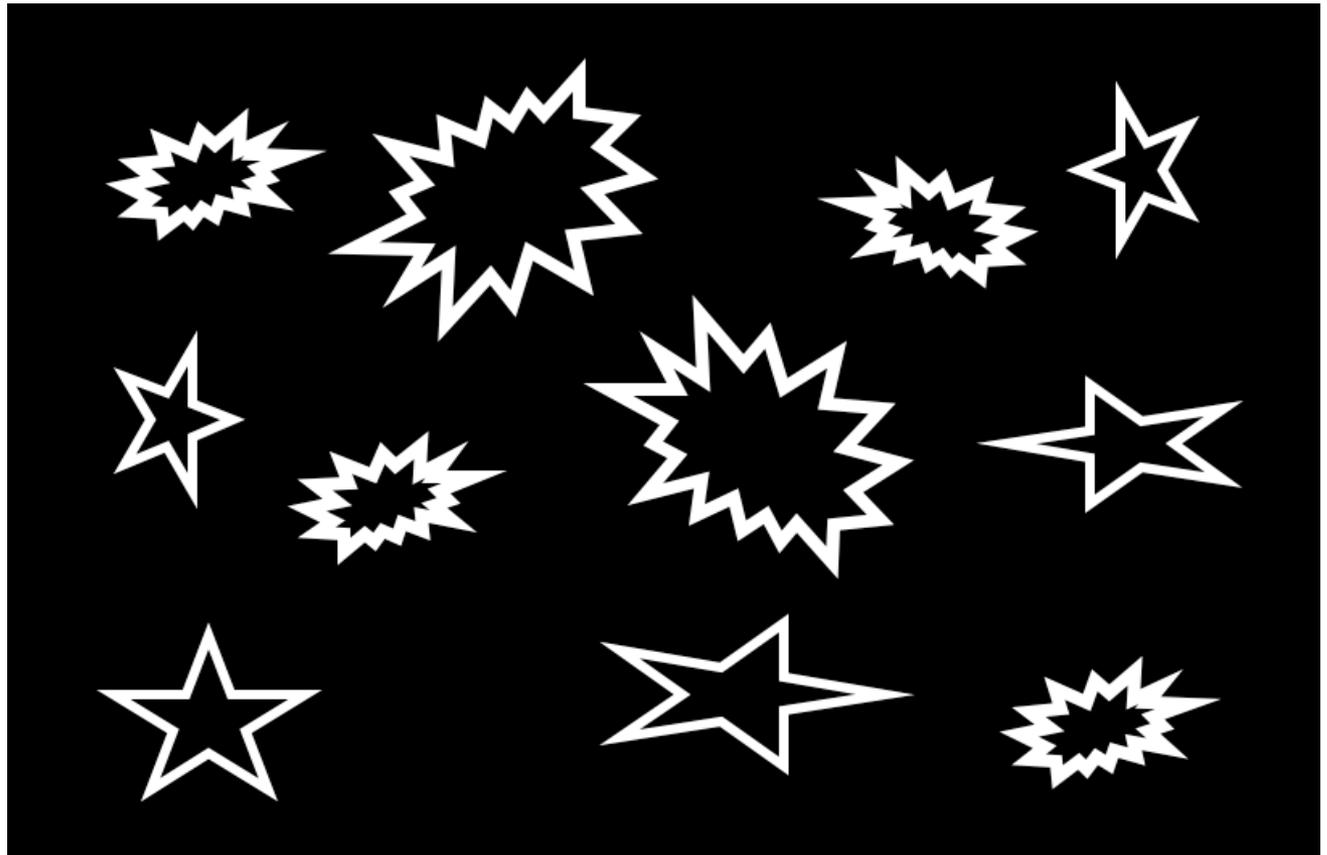

$$\max_{\bar{x}} C_{ff}(\bar{x}) = C_{ff}(0) = \int f(\bar{s})f(\bar{s})d\bar{s}$$

- A filter responds best when it matches a pattern that looks itself
- Strategy
  - Detect objects in images by correlation with “matched” filter

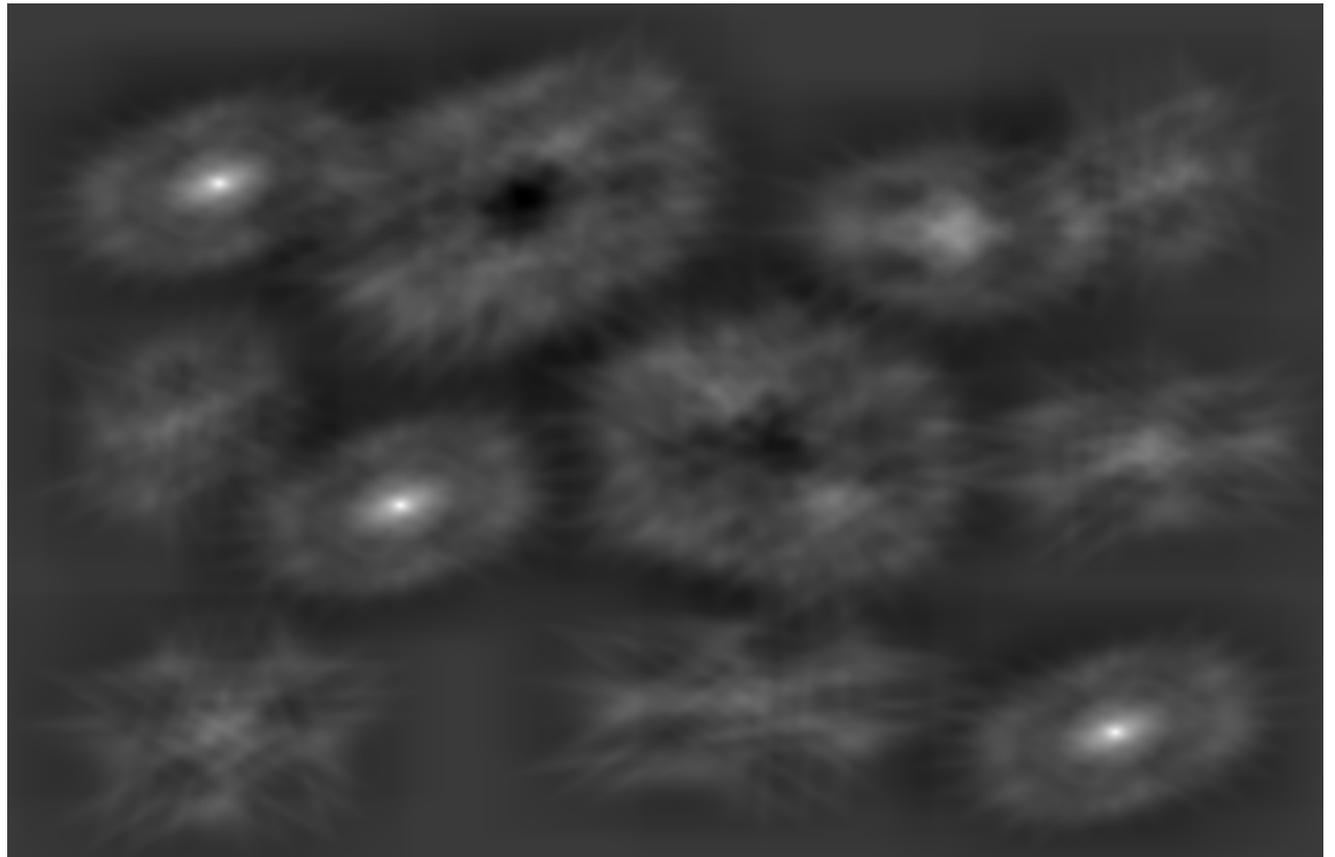

# Matched Filter Example

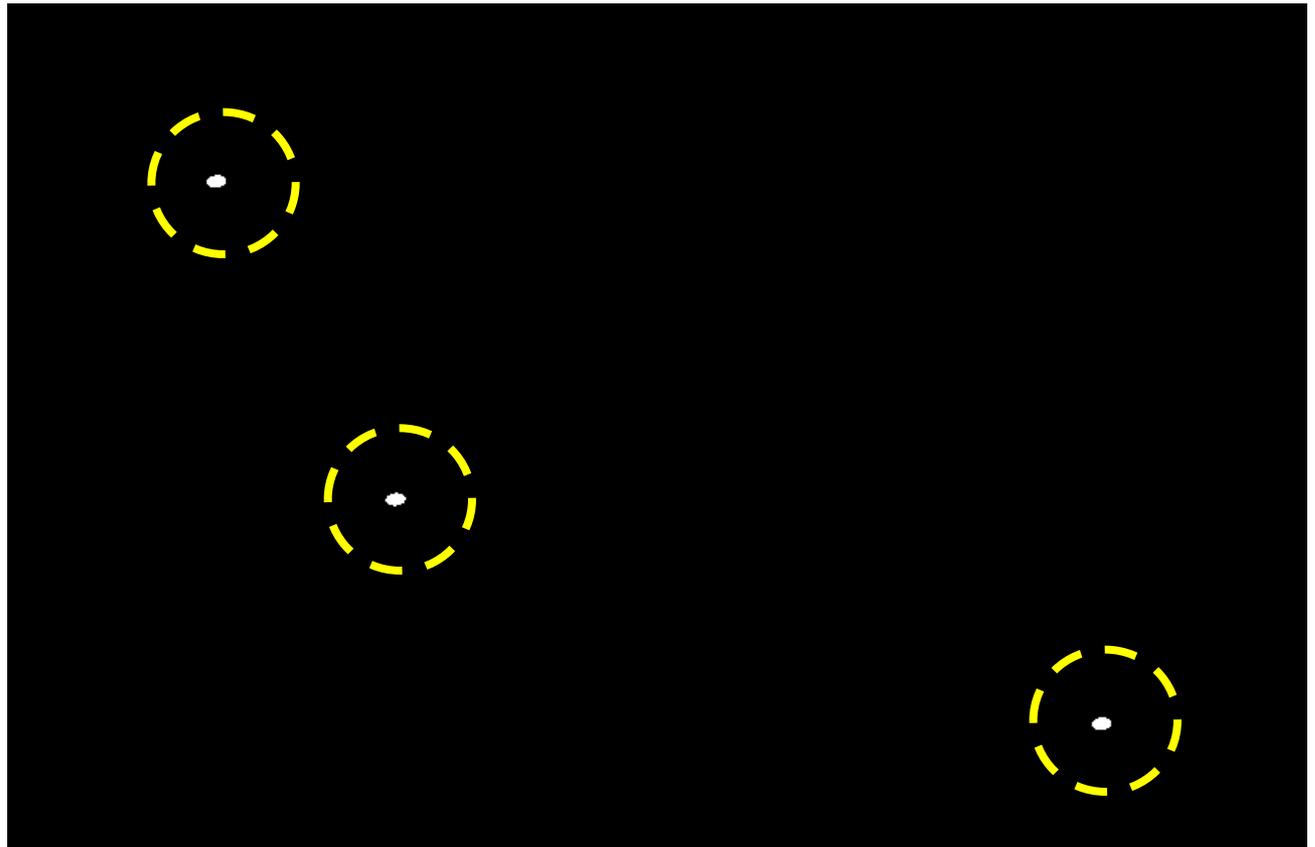

Trick: make  
sure kernel  
sums to zero

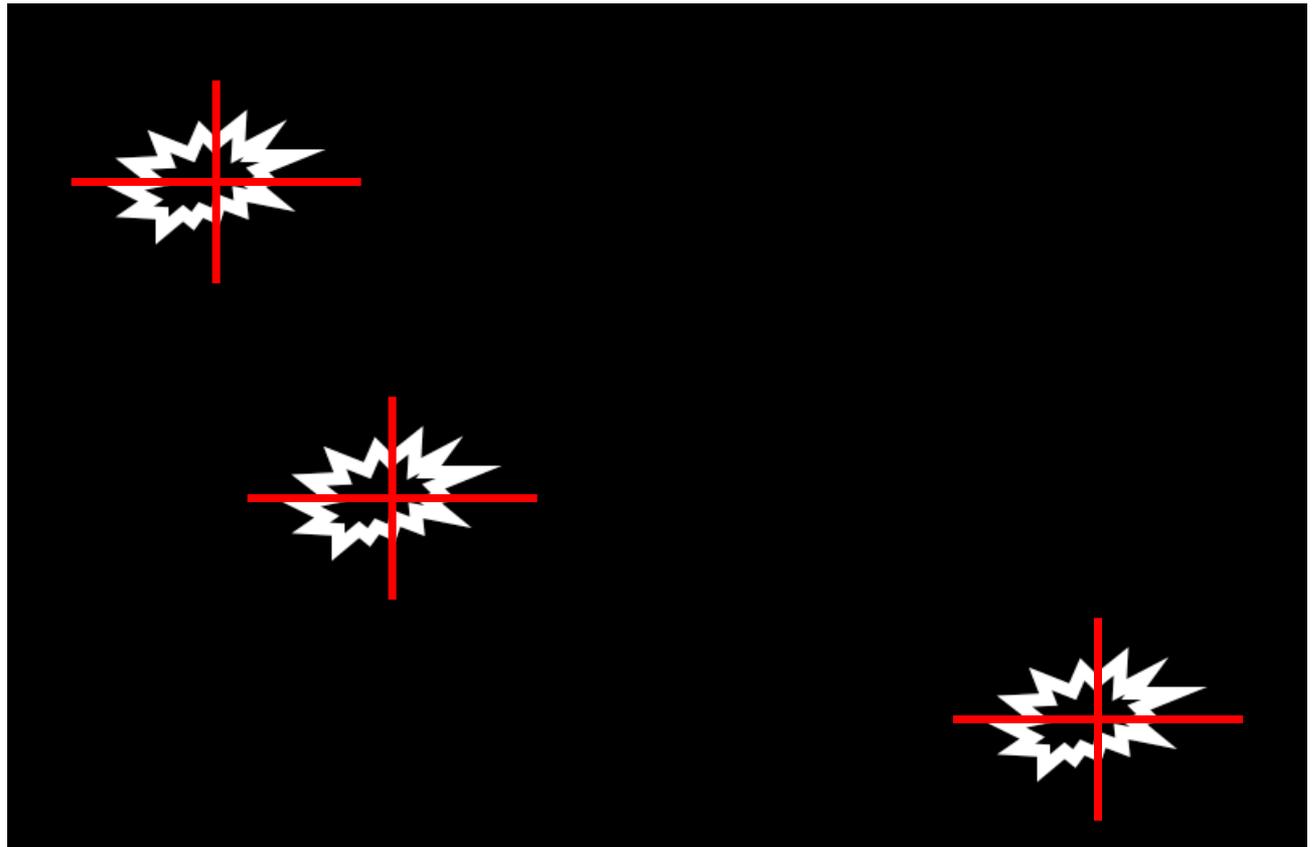

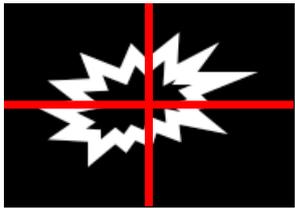

# Matched Filter Example: Correlation of template with image

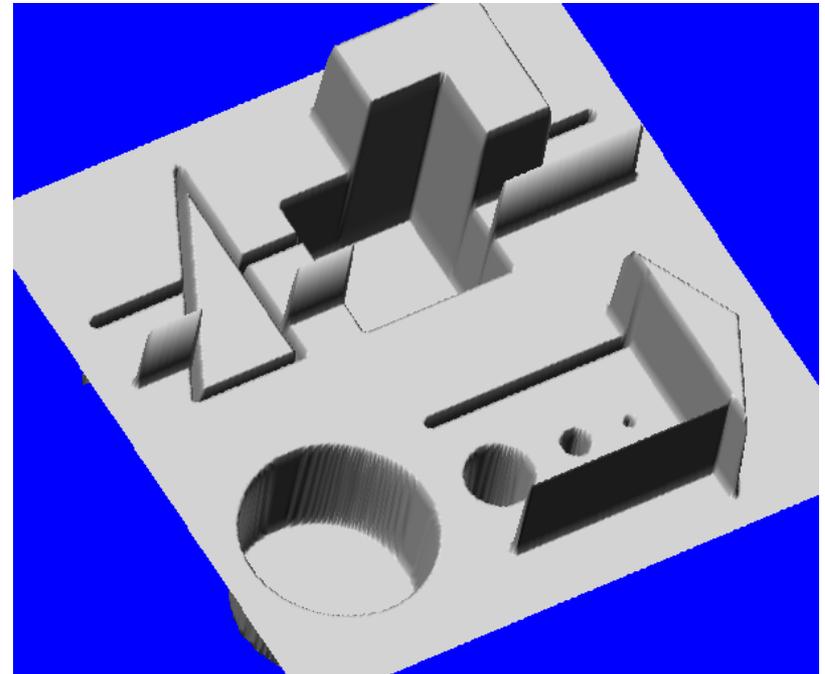

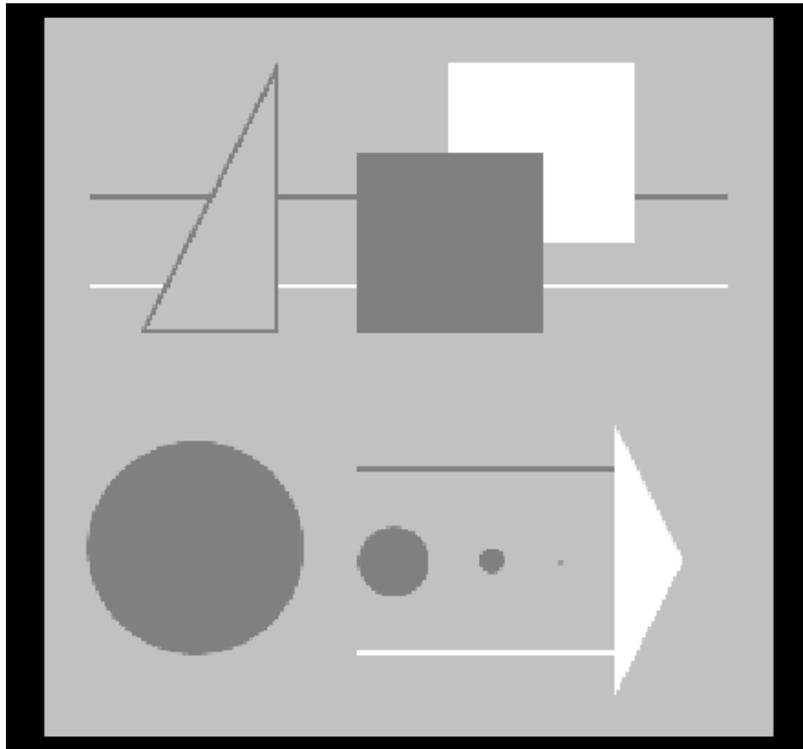

# Matched Filter Example: Thresholding of correlation results

# Matched Filter Example: High correlation $\rightarrow$ template found

# Digital Images: Boundaries are “Lines” or “Discontinuities”

Example: Characterization of discontinuities?

# Derivatives: Finite Differences

$$\frac{\partial f}{\partial x} \approx \frac{1}{2h} (f(x+1, y) - f(x-1, y))$$

$$\frac{\partial f}{\partial x} \approx w_{dx} \circ f \quad w_{dx} = \begin{array}{|c|c|c|} \hline -\frac{1}{2} & 0 & \frac{1}{2} \\ \hline \end{array}$$

$$\frac{\partial f}{\partial y} \approx w_{dy} \circ f \quad w_{dy} = \begin{array}{|c|} \hline -\frac{1}{2} \\ \hline 0 \\ \hline \frac{1}{2} \\ \hline \end{array}$$

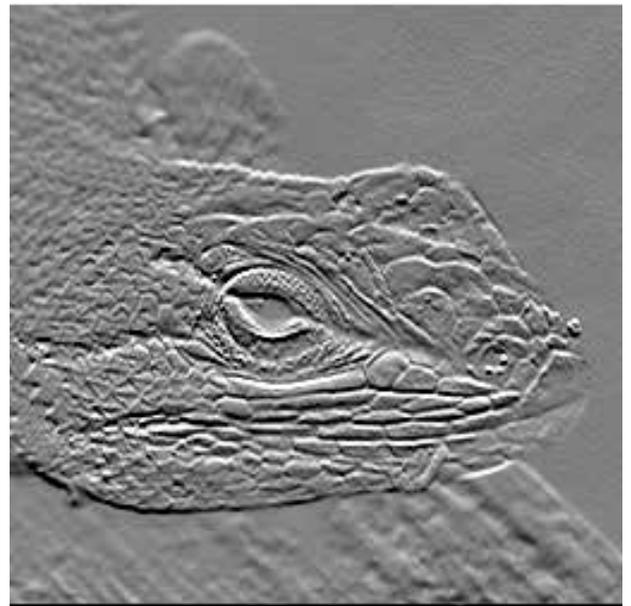

# Derivative Example

$$\begin{matrix} 0 & 0 & 0 \\ -1 & 0 & 1 \\ 0 & 0 & 0 \end{matrix}$$

$$\begin{matrix} 0 & -1 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{matrix}$$

I GOT UP TO HERE ON  
9/15/2010 (GUIDO)

# Convolution

Java demo: <http://www.jhu.edu/signals/convolve/>

- Discrete

$$g(x, y) = w(x, y) * f(x, y) = \sum_{s=-a}^a \sum_{t=-b}^b w(s, t) f(x - s, y - t)$$

- Continuous

$$g(x, y) = w(x, y) * f(x, y) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} w(s, t) f(x - s, y - t) ds dt$$

- Same as cross correlation with kernel transposed around each axis

- The two operations (correlation and convolution) are the same if the kernel is symmetric about axes

$$g = w \circ f = w^* * f$$

$w^*$  reflection of  $w$

# Convolution: Properties

- Shift invariant, linear
- Commutative

$$f * g = g * f$$

- Associative

$$f * (g * h) = (f * g) * h$$

- Others (discussed later):
  - Derivatives, convolution theorem, spectrum...

# Computing Convolution

- Compute time

- MxM mask

- NxN image

}  $O(M^2N^2)$

“for” loops are nested 4 deep

# Computing Convolution

- Compute time

- MxM mask

- NxN image

$O(M^2N^2)$

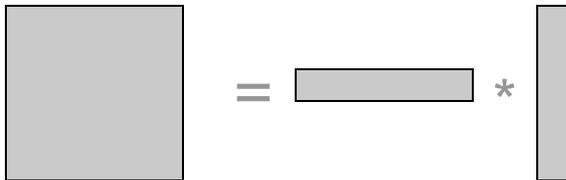

“for” loops are nested 4 deep

- Special case: *separable*

Two 1D kernels

$$w = w_x * w_y$$

$$w * f = \underbrace{(w_x * w_y) * f}_{O(M^2N^2)} = w_x * \underbrace{(w_y * f)}_{O(MN^2)}$$

# Separable Kernels

- Examples
  - Box/rectangle
  - Bilinear interpolation
  - Combinations of partial derivatives
    - $d^2f/dxdy$
  - Gaussian
    - Only filter that is both circularly symmetric and separable
- Counter examples
  - Disk
  - Cone
  - Pyramid

# Separability

$$g_{2D}(x, y; \sigma_1^2 + \sigma_2^2) = g_{1D}(x; \sigma_1^2) \otimes g_{1D}(y; \sigma_2^2)$$

```
DisplayTogetherArray[{Plot[gauss[x, σ = 1], {x, -3, 3}],  
  Plot3D[gauss[x, σ = 1] gauss[y, σ = 1], {x, -3, 3}, {y, -3, 3}],  
  ImageSize -> 440];
```

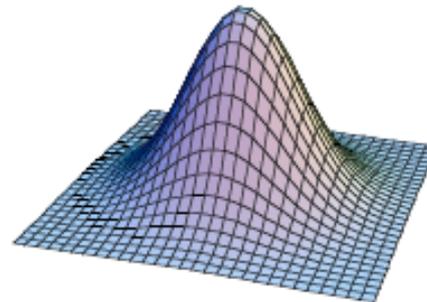

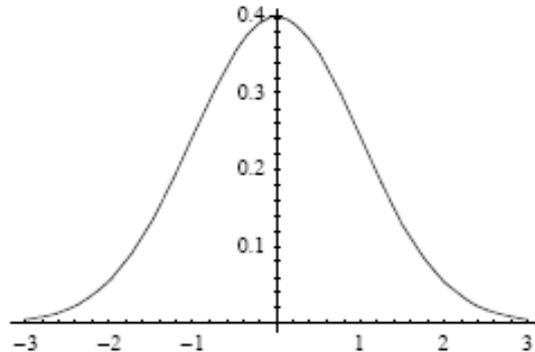

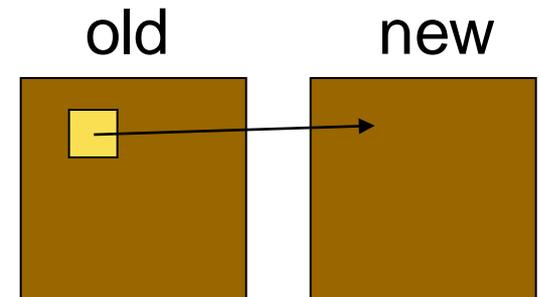

Figure 3.7 A product of Gaussian functions gives a higher dimensional Gaussian function. This is a consequence of the separability.

# Nonlinear Methods For Filtering

- Median filtering
- Bilateral filtering
- Neighborhood statistics and nonlocal filtering

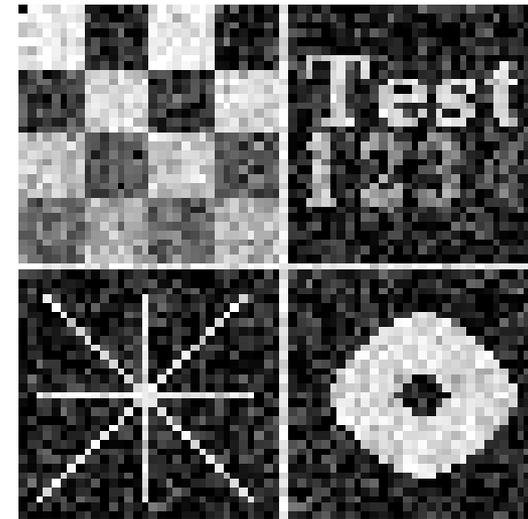

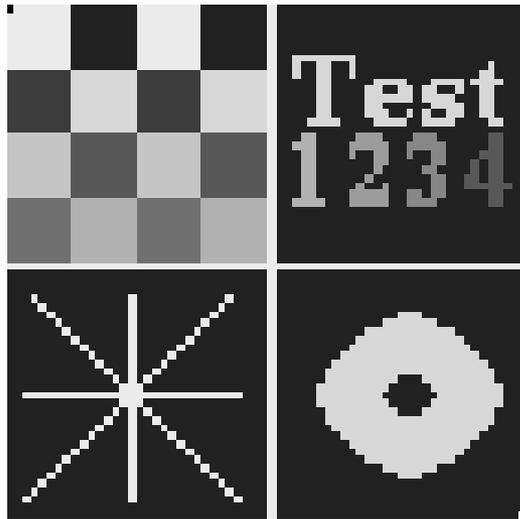

# Median Filtering

- For each neighborhood in image
  - Sliding window
  - Usually odd size (symmetric) 5x5, 7x7, ...
- Sort the greyscale values
- Set the center pixel to the median
- Important: use “Jacobi” updates
  - Separate input and output buffers
  - All statistics on the original image

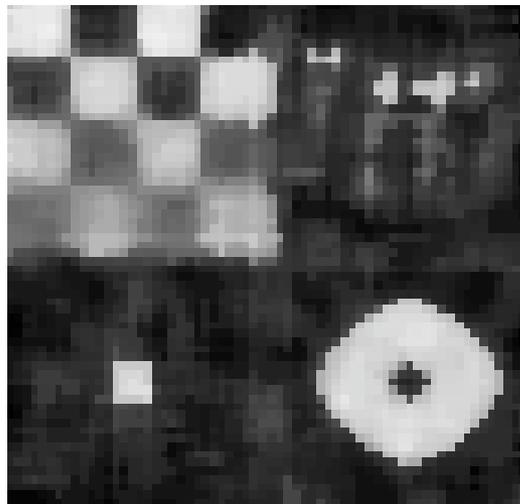

# Median vs Gaussian

Original

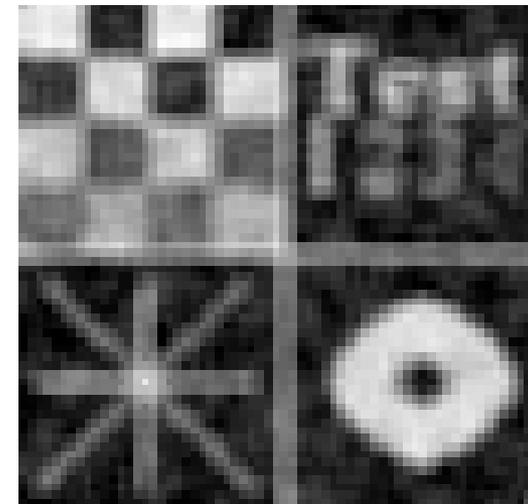

+  
Gaussian  
Noise

3x3  
Median

3x3 Box

# Median Filter

- **Issues**
  - Boundaries
    - Compute on pixels that fall within window
  - Computational efficiency
    - What is the best algorithm?
- **Properties**
  - Removes outliers (replacement noise – salt and pepper)
  - Window size controls size of structures
  - Preserves straight edges, but rounds corners and features

# Replacement Noise

- Also: “shot noise”, “salt&pepper”
- Replace certain % of pixels with samples from pdf
- Best filtering strategy: filter to avoid outliers

# Smoothing of S&P Noise

- It's not zero mean (locally)
- Averaging produces local biases

# Smoothing of S&P Noise

- It's not zero mean (locally)
- Averaging produces local biases

# Median Filtering

Median 3x3

Median 5x5

# Median Filtering

Median 3x3

Median 5x5

# Median Filtering

- Iterate

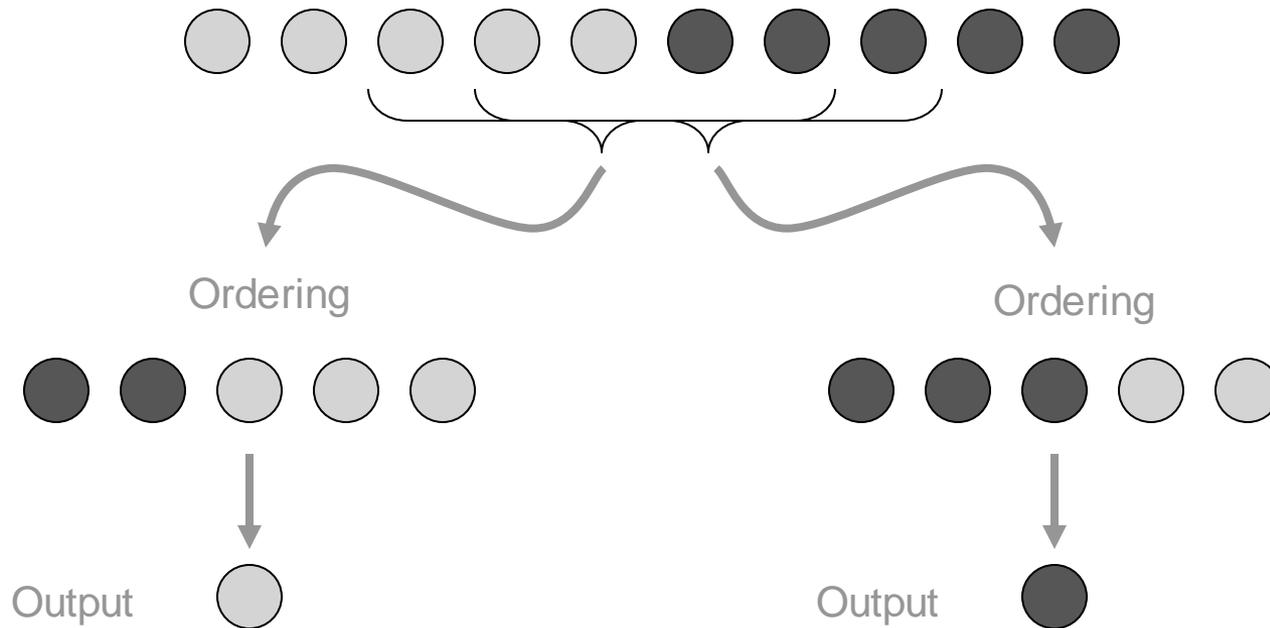

Median 3x3

2x Median 3x3

# Median Filtering

- Image model: piecewise constant (flat)

# Order Statistics

- Median is special case of order-statistics filters
- Instead of weights based on neighborhoods, weights are based on ordering of data

Neighborhood  
 $X_1, X_2, \dots, X_N$

Ordering  
 $X_{(1)} \leq X_{(2)} \leq \dots \leq X_{(N)}$

Filter  $F(X_1, X_2, \dots, X_N) = \alpha_1 X_{(1)} + \alpha_2 X_{(2)} + \dots + \alpha_N X_{(N)}$

Neighborhood average (box)

$$\alpha_i = 1/N$$

Median filter

$$\alpha_i = \begin{cases} 1 & i = (N + 1)/2 \\ 0 & \text{otherwise} \end{cases}$$

Trimmed average (outlier removal)

$$\alpha_i = \begin{cases} 1/M & (N - M + 1)/2 \leq i \leq (N + M + 1)/2 \\ 0 & \text{otherwise} \end{cases}$$

# Piecewise Flat Image Models

- Image piecewise flat -> average only within similar regions
- Problem: don't know region boundaries

# Piecewise-Flat Image Models

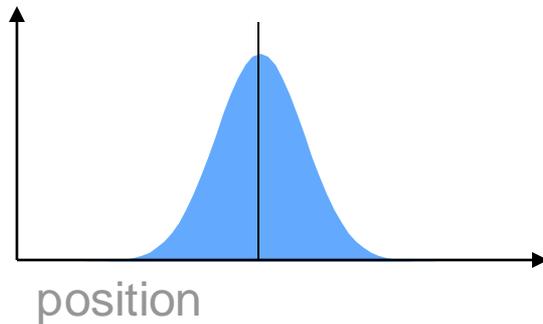

- Assign probabilities to other pixels in the image belonging to the same region
- Two considerations
  - Distance: far away pixels are less likely to be same region
  - Intensity: pixels with different intensities are less likely to be same region

# Piecewise-Flat Images and Pixel Averaging

Distance (kernel/pdf)

$$G(\mathbf{x}_i - \mathbf{x}_j)$$

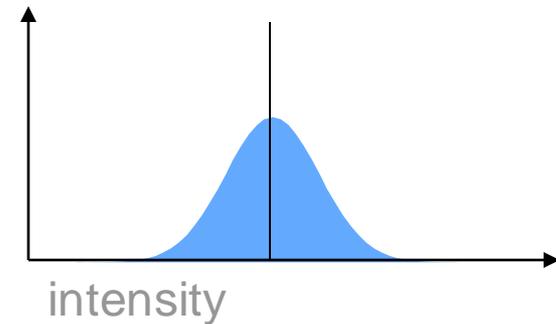

Prob  
pixel  
belongs  
to same  
region  
as  $i$

Distance (pdf)

$$H(f_i - f_j)$$

Prob  
pixel  
belongs  
to same  
region  
as  $i$

# Bilateral Filter

- Neighborhood – sliding window
- Weight contribution of neighbors according to:

$$f_i \leftarrow k_i^{-1} \sum_{j \in N} f_j G(\mathbf{x}_i - \mathbf{x}_j) H(f_i - f_j)$$

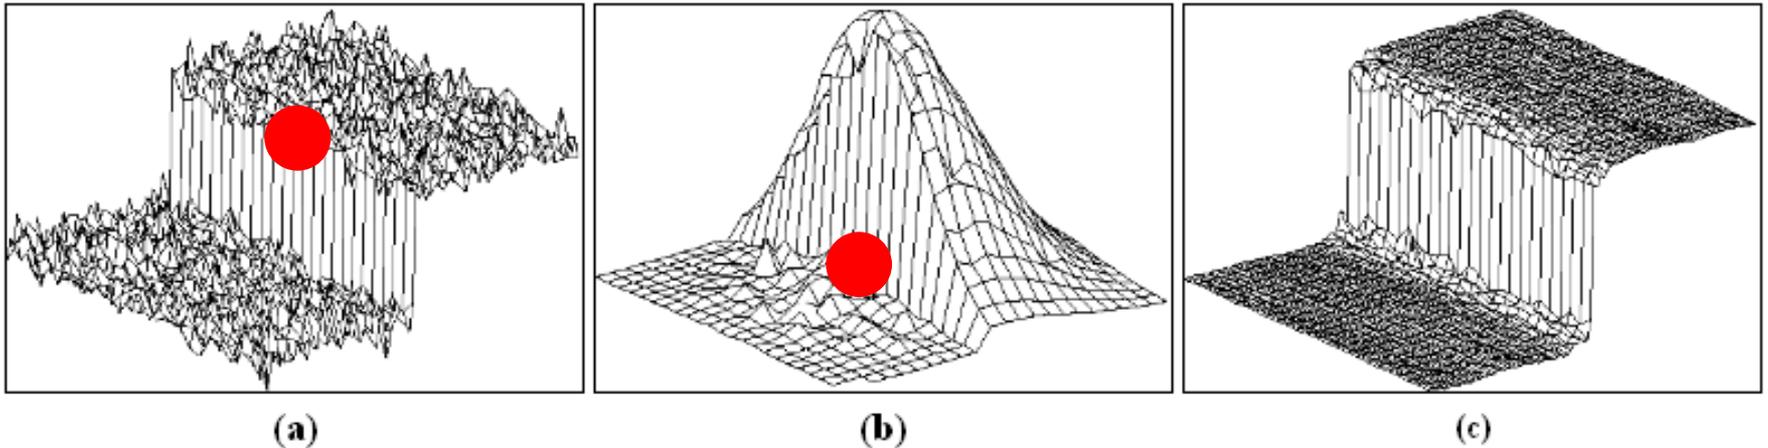

$$k_i = \sum_{j \in N} G(\mathbf{x}_i - \mathbf{x}_j) H(f_i - f_j)$$

normalization: all weights add up to 1

- G is a Gaussian (or lowpass), as is H, N is neighborhood,
  - Often use  $G(r_{ij})$  where  $r_{ij}$  is distance between pixels
  - Update must be normalized for the samples used in this (particular) summation
- Spatial Gaussian with extra weighting for intensity
  - Weighted average in neighborhood with downgrading of intensity outliers

# Bilateral Filter

Replaces the pixel value at  $x$  with an average of similar and nearby pixel values.

When the bilateral filter is centered, say, on a pixel on the bright side of the boundary, the similarity function  $s$  assumes values close to one for pixels on the same side, and values close to zero for pixels on the dark side. The similarity function is shown in figure 1(b) for a  $23 \times 23$  filter support centered two pixels to the right of the step in figure 1(a).

# Bilateral Filtering

Replaces the pixel value at  $x$  with an average of similar and nearby pixel values.

Gaussian Blurring

Bilateral

# Bilateral Filtering

Gaussian Blurring

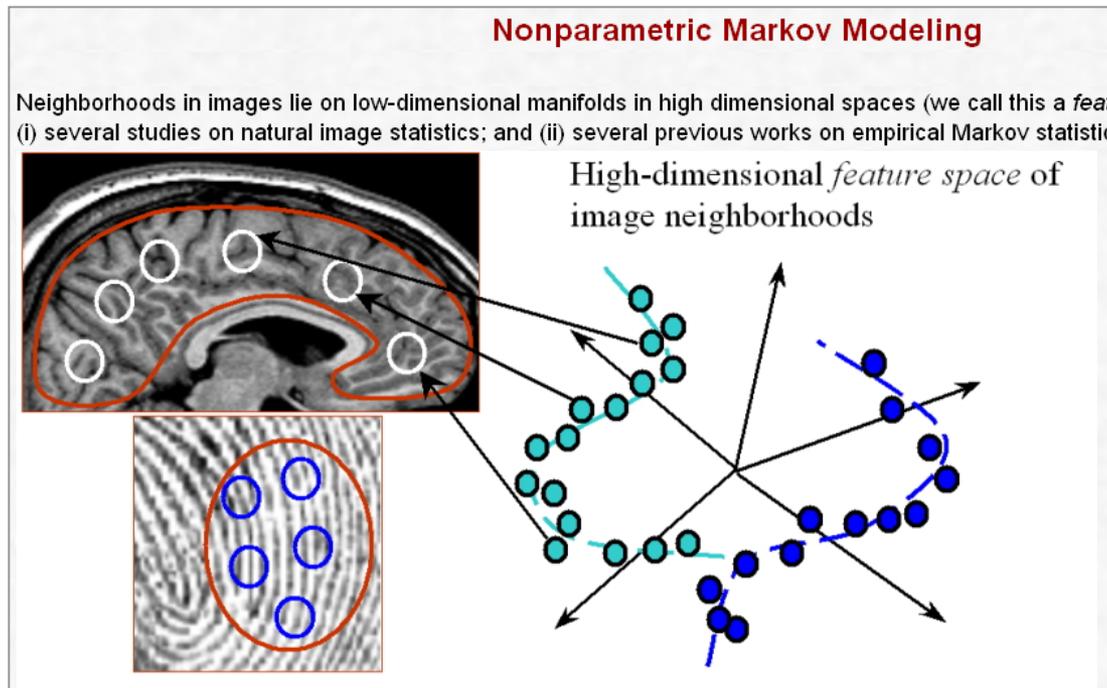

Bilateral

# Nonlocal Averaging

- Recent algorithm
  - NL-means, Baudes et al., 2005
  - UINTA, Awate & Whitaker, 2005
- Different model
  - No need for piecewise-flat
  - Images consist of some set of pixels with similar neighborhoods → average several of those
    - Scattered around
      - General area of a pixel
      - All around
- Idea
  - Average sets of pixels with similar neighborhoods

# UINTA: Unsupervised Information-Theoretic Adaptive Filtering : Excellent Introduction and Additional Readings (Suyash P. Awate)

<http://www.cs.utah.edu/~suyash/pubs/uinta/>

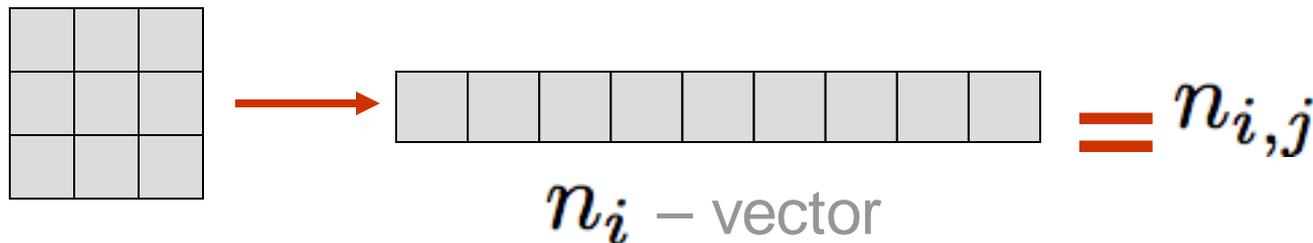

Suyash P. Awate, Ross T. Whitaker

[Unsupervised, Information-Theoretic, Adaptive Image Filtering with Applications to Image Restoration](#)

*IEEE Trans. Pattern Analysis & Machine Intelligence (TPAMI)* 2006, Vol. 28, Num. 3, pp. 364-376

# Nonlocal Averaging

- Strategy:
  - Average pixels to alleviate noise
  - Combine pixels with similar neighborhoods
- Formulation
  - $n_{i,j}$  – vector of pixels values, indexed by  $j$ , from neighborhood around pixel  $i$

# Nonlocal Averaging Formulation

- Distance between neighborhoods

$$d_{i,k} = d(n_i, n_k) = \|n_i - n_k\| = \left( \sum_{j=1}^N (n_{i,j} - n_{k,j})^2 \right)^{\frac{1}{2}}$$

- Kernel weights based on distances

$$w_{i,k} = K(d_{i,k}) = e^{-\frac{d_{i,k}^2}{2s^2}}$$

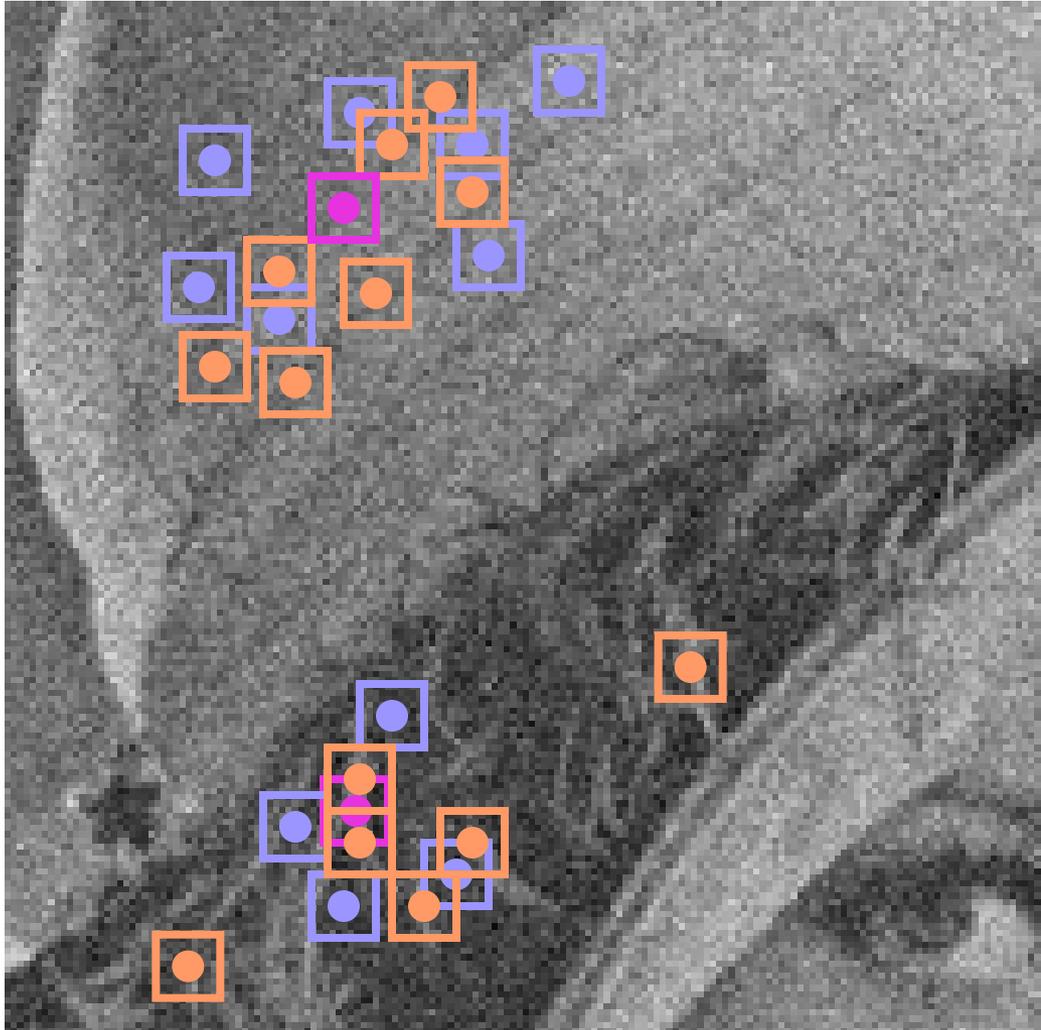

- Pixel values of k neighborhoods:  $f_k$

# Averaging Pixels Based on Weights

- For each pixel,  $i$ , choose a set of pixel locations  $k$ :
  - $k = 1, \dots, M$
  - Average them together based on neighborhood weights (prop. to intensity pattern difference)

$$g_i = \frac{1}{\sum_{k=1}^M w_{i,k}} \sum_{k=1}^M w_{i,k} f_k$$

# Nonlocal Averaging

# Some Details

- Window sizes: good range is 5x5- >11x11
- How to choose samples:
  - Random samples from around the image
    - UINTA, Awate&Whitaker
  - Block around pixel (bigger than window, e.g. 51x51)
    - NL-means
- Iterate
  - UNITA: smaller updates and iterate

# NL-Means Algorithm

- For each pixel,  $p$ 
  - Loop over set of pixels nearby
  - Compare the neighborhoods of those pixels to the neighborhood of  $p$  and construct a set of weights
  - Replace the value of  $p$  with a weighted combination of values of other pixels
- Repeat... but 1 iteration is pretty good

# Results

Noisy image (range 0.0-1.0)

Bilateral filter (3.0, 0.1)

# Results

Bilateral filter (3.0, 0.1)

NL means (7, 31, 1.0)

# Results

Bilateral filter (3.0, 0.1)
