1 What's New?

In this section, we highlight the latest additions to map3d in the (vain?) hope that people will read at least this much of the manual and be able to quickly make use of the latest and greatest that the program offers.

1.1 Version 6.0: March, 2004

This is the first version of the "new" map3d with a GTK-based GUI. We are getting even closer to the functionality of the old GL based version. Even more important, there are also several new interactive features unique to the OpenGL+GTK version.

Some of the specific things that you should notice over previous versions include:

New look and feel: with the move from GLUT to gtk has come a whole new look and feel for map3d. Fonts are new and much nicer than before and all the menus and dialog boxes have a cleaner, more professional look than before.

New GUIs: There are several new GUIs that you can open through the menus. Perhaps the most prominent is the "Files Dialog", through which you can interactively load and reload files and data windows. There is also a scaling dialog, from which you can change the scaling parameters with one click, and a saving dialog where you can save geometry and images (soon to have state-saving and movie-saving features).

Interactive Control: Now you can select one of many parameters to adjust by pressing the + or - key, including font sizes, contour thickness, etc.

Keyboard Transformations: Now you can use the keyboard to rotate, translate and scale, and even edit nodes' positions in your geometry.

Bug fixes: not that the previous version had any bugs, but we found a few(!) things to fix.

1.2 In the works ("vapourware")

A small sampler of things that are in the works:

- Reading of Time Series container files.
- Proper reading of the container files in the *graphicsio* file system.
- Dynamic menus that indicate the current parameter selections (in progress).
- Saving and reading settings to keep your favorite settings around next time.
- Remote Control of the animations and user interventions for making videos.
- New display modes for the display of vectors.
- We are trying to fix the bugs listed on the bugs page (see Section 10) as quickly as we can.

CVRTI/SCI Manual: map3d

2 Introduction

This document describes the function and usage of the program map3d, a scientific visualization application originally developed at the Nora Eccles Harrison Cardiovascular Research and Training (CVRTI) and now under continued development and maintenance at the Scientific Computing and Imaging Institute (SCI) at the University of Utah. The original purpose of the program was to interactively view scalar fields of electric potentials from measurements and simulations in cardiac electrophysiology. Its present utility is much broader but continues to focus on viewing three-dimensional distributions of scalar values associated with an underlying geometry consisting of node points joined into surface or volume meshes.

map3d has been the topic of some papers $^{1-4}$ and a technical report 5 and we'd love it if you would reference at least one of them (perhaps 3 or 4 are the easiest ones to get copies of) as well as this manual when you publish results using it. There have been many many more papers that use map3d and the list keeps growing. $^{3-30}$

2.1 Acknowledgments

The history of map3d goes back to 1990 and the first few hundred lines of code were the product of a few hours work by Mike Matheson, an inspired visualization specialist, now with SGI in Salt Lake City. This was my introduction to GL and C and this program became my personal sand box to play in. Along the way, Phil Ershler made valuable contributions in figuring out the magic of Formslib for some user interface controls and developing with me graphicsio, the geometry and data file library that supports map3d. Ted Dustman has recently taken up maintenance and extensions of graphicsio and remains my main man when I need programming lessons.

This is one in a series of "new" versions of map3d, the series (labeled 5.x or above) that marks the move from GL to OpenGL library and thus to becoming truly portable. In fact, we call the old one map3dGL now to indicate its links to SGI's original GL library. We seem permanently stuck in the middle of this big conversion project, moving support to OpenGL and adding lots of power as we convert functionality. The most recent news, and the reason for the version 6.x, is the move to gtk as the GUI library with which we create all the dialog and display elements of the program. We hope this move will allow us to dramatically extend the set of dialog boxes map3d offers and version 6.0 contains the first set of examples.

There are some people who have been instrumental in the process and deserve special mention. Chris Moulding is a graphics programmer and general software whiz who surveyed my sand box architecture, pulled together the essential walls, created new ways to make rooms, and still left lots of the sand box around so we could continue to play. From version 5.2 onward, Bryan Worthen replaced Chris and really has found the spirit of map3d and become the main driving force behind the actual work of coding and fixing. He strayed off to some other project for a while, but never lost his love for map3d; now I'm really pleased that he has returned to pick up the torch again. Most recently, J.R. Blackham has joined the team while still an undergraduate in Computer Science at Utah.

The largest thanks must go to the users of map3d, who provided the real inspiration and identified the needs and opportunities of such a program. Among the most supportive and helpful are Bruno Taccardi, Bonnie Punske, and Bob Lux, all colleagues of mine at the CVRTI. Dana Brooks and his students from Northeastern University are also regular users who have provided many suggestions and great enthusiasm. Also invaluable in the constant improvement of the program are my post docs, Jeroen Stinstra, and graduate student Quan Ni, Rich Kuenzler, Bulent Yilmaz, Bruce Hopenfeld, Shibaji Shome, Lucas Lorenzo, Andrew Shafer, and Zoar Englemann. They give me new energy and remind me why I am a professor.

The first user and long-time collaborator and friend was Chris Johnson and this new version of map3d is possible because of the success he and I have had in creating the SCI Institute and specifically the NIH/NCRR Center for Geometric Modeling, Simulation, and Visualization in Bioelectric Field Problems (www.sci.utah.edu/ncrr).

We gratefully acknowledge the financial support that has come from the NIH, National Center for Research Resources (NCRR) the Nora Eccles Treadwell Foundation, and the University of Utah, which provides us with space and materials to create this sand box. The Nora Eccles Treadwell Foundation has also provided support for the development of map3d and the huge pile of data we have used it to analyze.

Rob MacLeod, April 7, 2004.

2.1.1 Libraries used by map3d

map3d incorporates the functionality of several external libraries. They are:

- GTK The GIMP Toolkit Copyright (C) 1995-1997 Peter Mattis, Spencer Kimball and Josh MacDonald
- GtkGLExt GtkGLExt OpenGL Extension to GTK+ Copyright (C) 2002-2004 Naofumi Yasufuku
- PNG Copyright (c) 1998-2002 Glenn Randers-Pehrson
- Jpeglib Copyright (C) 1991-1998, Thomas G. Lane.

We use GTK and GtkGLExt to interface with the window manager to give us windows with OpenGL capability, as well as giving us widgets we need for interactive control. We use PNG and JpegLib to be able to save .png and .jpg images of map3d.

All four of these libraries are covered by the GNU LGPL, which is included in the distribution of map3d.

3 Installation

3.1 System requirements

map3d is written in standard C/C++ and uses the OpenGL and GTK+ libraries, both choices made to ensure broad portability of the program. This first OpenGL+GTK version of map3d targets three platforms and we list the requirements and recommendations for each below. Additional platforms will follow—and follow even faster if you send us a machine to play on.

All platforms:

Requirements for all systems		
OpenGL libraries (GL and GLU) version $1.1 + 1$		
OpenGL/window interface library (GLX)		
GTK+ libraries and dependencies	version 2.0+	

SGI: map3d runs on virtually any SGI that will support Irix version 6.5+. We have tested it on Indigo2, O2, Octane, and Origin workstations running various flavors of Irix 6.5. If you need a version for a different SGI configuration, please let us know (map3d@sci.utah.edu)

Requirements		
Operating System	Irix 6.5+	
Architecture	mips3 or mips4 (maybe mips2)	
Applications Binary Interface	n32 or 64	
Recommendations		
Hardware	Texture mapping hardware	
	128 MB main memory	

Linux (i386): map3d requires the OpenGL library, which is available as the mesa library at www.mesa3d.org for any Linux platform. For better performance, graphics cards from companies such as nVidia (www.nvidia.com) usually provide OpenGL libraries.

Requirements		
Operating System	kernel 2.2.x	
Architecture	i386 (+ maybe PPC)	
Applications Binary Interface	libc2.1	
Recommendations		
Window system	XFree86 version 4.0 +	
Hardware	3D graphics card (nVidia, 3dfx, ati)	
	128 MB main memory	

Windows:

Requirements		
Operating System	W2K/NT4.0/9x	
Architecture	i386	
Applications Binary Interface	win32	
Recommendations		
Hardware	3D graphics card (nVidia, 3dfx, ati)	
	128 MB main memory	

3.2 General Installation

Unfortunately, as this is the first version of map3d with GTK+, it is not as easy as other versions where you could just download and run. We hope to be able to do that again in the future, but for now we will attempt to make it as easy as possible for you. Simplified instructions will be in a README file which comes with each package, and are also listed below:

To download the software, use this URL www.sci.utah.edu/software/map3d.html, and click on the "Download" button. You'll need to sign into the SCI archive. For each of the installation instructions below, you can grab those file from this page.

To test the installation, use the test files that accompany this distribution. Each has some script files included that show how to call and execute map3d.

3.3 SGI Installation Instructions

The SGI installation is relatively straightforward. You'll need to download map3d's dependencies, then download map3d itself.

3.3.1 SGI Dependencies

There are two phases to this part. First we need to get GTK+ and its dependencies. The easiest way to do this is for SGI is to run a browser with root access and go to SGI's freeware site at http://freeware.sgi.com. On that page near the bottom there should be a link to a prereq calculator. Click on that link, and in the Freeware Product box, select fw_gtk2+ (make sure you don't select fw_gtk+). Submit the query. You should see a list similar to this:

```
fw_atk [relnotes] [prereqs] [install]
fw_expat [relnotes] [prereqs] [install]
fw_freetype2 [relnotes] [prereqs] [install]
fw_gettext [relnotes] [prereqs] [install]
fw_glib2 [relnotes] [prereqs] [install]
fw_libjpeg [relnotes] [prereqs] [install]
fw_libpng [relnotes] [prereqs] [install]
fw_libz [relnotes] [prereqs] [install]
fw_pango [relnotes] [prereqs] [install]
fw_tiff [relnotes] [prereqs] [install]
```

To install them, click on the install link one by one (and follow the instructions in the dialog boxes).

IMPORTANT - when you install libz - it will mention something about a security library being removed. When you install libz, allow it to do this. On the subsequent libraries, it will mention that the security package conflicts with libz, on these packages, have it continue without installing the security package.

Install them in the order:

```
gettext
expat
freetype2
atk
glib2
pango
libjpeg
libtiff
libz
libpng
```

After you've done all of these, click on the alphabetical link, and click on the install buton that corresponds to libgtk2+-2.0.6.

If for some reason, the prereq calculator isn't there or isn't working, go to the alphabetical index and install the above in the order specified.

The next part is to download gtkglext, the library that supports OpenGL for GTK widgets. If your GTK version is 2.0.6 (you can find out by looking at gtkversion.h which will be where you installed gtk (normally /usr/freeware/include/gtk-2.0/gtk/gtkversion.h), and look for GTK_MAJOR_VERSION, GTK_MINOR_VERSION, and GTK_MICRO_VERSION. There will be numbers on the same lines as each of these, and if you put them together it will be something like 2.0.6). If you are using this version download gtkglext-sgi.tar.gz from the map3d download page http://www.sci.utah.edu/software/map3d.html and follow these instructions:

```
cd <download directory>
gunzip gtkglext-sgi.tar.gz
tar xf gtkglext-sgi.tar
cp libgtkglext-x11-1.0.so.0 /usr/local/lib
cp libgdkglext-x11-1.0.so.0 /usr/local/lib
```

You can copy them to some directory other than /usr/local/lib if you wish.

If this doesn't work, you will need to download the gtkglext source and compile it yourself (don't worry—if your gtk is properly set up, this will be very easy). Download the sources from Source Forge http://sourceforge.net/projects/gtkglext and follow these instructions:

```
cd <download directory>
gunzip gtkglext-1.0.6.tar.gz
tar xf gtkglext-1.0.6.tar
cd gtkglext-1.0.6
configure
make
make install
```

If you don't want these to end up in /usr/local/lib, you need to

```
configure --prefix=<dir>
```

where dir is where you want to put the libraries (The libraries will be in dir/lib).

3.3.2 SGI Executable

Download the map3d-6.0-irix.tar.gz file from the map3d download page and unzip it to a directory of your choice. We will call that RUN-DIR. This is the directory from which you will run map3d.

To run map3d, you will need to make sure that all the libraries are in your LD_LIBRARY_PATH environment variable. For this we will assume that your gtk libraries are in /usr/freeware/lib32 and your gtkglext libraries are in /usr/local/lib. Do the following:

```
tcsh users:
setenv LD_LIBRARY_PATH /usr/freeware/lib32:/usr/local/lib:$LD_LIBRARY_PATH
```

or bash users:

```
export LD_LIBRARY_PATH=/usr/freeware/lib32:/usr/local/lib:$LD_LIBRARY_PATH
```

you might want to put this line in your .cshrc or .profile file to avoid having to run this multiple times.

3.4 Linux Installation Instructions

The Linux installation is relatively straightforward. You'll need to download map3d's dependencies, then download map3d itself.

3.4.1 Linux Dependencies

There are two phases to this part. First we need to get GTK+ and its dependencies. The easiest way to do this is from your distribution's installation CDs, or you can download the RPMs at www.rpmfind.net.

To get the dependencies from your distribution, run the Package Manager (Add/Remove Applications, configure-packages or something of that sort). Search for gtk, and install gtk2 (if you can't find that directly, then installing the gnome environment will take care of it).

To get the dependencies from the internet, navigate your favorite browser to www.rpmfind.net, and search for gtk-2.0. Try to find one that matches your distribution (redhat, mandrake, etc.). We directly support development for gtk2-2.2.1 and gtk2-2.0.6, so if you can find one of these that would be encouraged.

The next part is to download gtkglext, the library that supports OpenGL for GTK widgets. As of this release, this is not standard in most distributions. If your GTK version is 2.0.6 or 2.2.1 (you can find out by looking at gtkversion.h which will be where you installed gtk (normally /usr/include/gtk-2.0/gtk/gtkversion.h), and look for GTK_MAJOR_VERSION, GTK_MINOR_VERSION, and GTK_MICRO_VERSION. There will be numbers on the same lines as each of these, and if you put them together it will be something like 2.2.1). If you are using one of these versions download gtkglext-linux-2.2.1.tar.gz or gtkglext-linux-2.0.6 from the map3d download page and follow these instructions:

```
cd <download directory>
gunzip gtkglext-linux-<version>.tar.gz
tar xf gtkglext-linux-<version>.tar
cp libgtkglext-x11-1.0.so.0 /usr/local/lib
cp libgdkglext-x11-1.0.so.0 /usr/local/lib
```

You can copy them to some directory other than /usr/local/lib if you wish.

If this doesn't work, you will need to download the gtkglext source and compile it yourself (don't worry—if your gtk is properly set up, this will be very easy). Download the sources from Source Forge http://sourceforge.net/projects/gtkglext and follow these instructions:

```
cd <download directory>
gunzip gtkglext-1.0.6.tar.gz
tar xf gtkglext-1.0.6.tar
cd gtkglext-1.0.6
configure
make
make install
```

If you don't want these to end up in /usr/local/lib, you need to

```
configure --prefix=<dir>
```

where dir is where to put the libraries.

3.4.2 Linux Executable

Download the map3d-6.0-linux.tar.gz file from the map3d() download page and unzip it to a directory of your choice. We will call that RUN-DIR. This is the directory from which you will run map3d.

To run map3d, you will need to make sure that all the libraries are in your LD_LIBRARY_PATH environment variable. For this we will assume that your gtk libraries are in /usr/lib and your gtkglext libraries are in /usr/local/lib. Do the following: tcsh users:

```
setenv LD_LIBRARY_PATH /usr/local/lib:$LD_LIBRARY_PATH
```

or

bash users:

CVRTI/SCI Manual: map3d

export LD_LIBRARY_PATH=/usr/local/lib:\$LD_LIBRARY_PATH

you might want to put this line in your .cshrc or .profile file to avoid having to run this multiple times.

3.5 Windows Installation Instructions

The Windows installation is relatively straightforward. You'll need to download map3d's dependencies, then download map3d itself.

3.5.1 Windows Dependencies

Download the map3d-win-environment.zip file from the map3d download page and unzip it into a location of your choice - we will call that INSTALL-DIR. It will create a directory called INSTALL-DIR\map3d.

Add INSTALL-DIR\map3d\lib to your path. To do this, open the Control Panel, select System, and click on the 'Advanced' tab on the top of the screen. Click on the Environment Variables button. You should see a variable called Path or PATH in the System Variables section. Click on it, and select Edit. Go to the end of the line, add a semi-colon (;) and type INSTALL-DIR\map3d\lib.

3.5.2 Windows Executable

There is an executable of map3d in the environment directory. We have also placed an executable here to facilitate future downloads, so you only have to download the environment once. If you wish, download the map3d-6.0-windows.zip file from the map3d download page and unzip it to a directory of your choice. We will call that RUN-DIR. This is the directory from which you will run map3d.

3.6 Documentation

This document should have reached you either as a pdf file or via the map3d web site. If you would like more copies or the latest version, go to the same web site and look for the links under Documentation:

www.sci.utah.edu/software/map3d.html

3.7 Bug reporting

We want to hear your response to using map3d and especially to learn about any bugs you may find. They may be features, rather than bugs, but if so, we will be happy to hear your impressions.

To submit a bug report please send email to map3d@sci.utah.edu or point your browser at software.sci.utah.edu/bugzilla (you will need to register your e-mail address) with the following information:

- 1. Type and version of the operating system and hardware you are using.
- 2. Version of map3d.
- 3. Description of the bug/feature you encountered.
- 4. Suggestions for fixing the bug or altering the program behavior.

3.8 How to reach us

We have established an email address for map3d, map3d@sci.utah.edu, and web pages within the website www.sci.utah.edu/ncrr dedicated to map3d. There is also a majordomo mailing list for map3d users called map3d-users@sci.utah.edu. To subscribe to this list, send email to majordomo@sci.utah.edu with the following in the message body

subscribe map3d-users

CVRTI/SCI Manual: map3d

Please let us know how you use map3d and how we can make it better for your purposes. We can only develop this program with continued support and the best way to achieve this is to show that others use the program and find it helpful.

4 Usage

This version of map3d provides two ways to load files. The first is via the command line, which is described in this section. The second is via the files window (see Section 8.5.1)

This is a subset of map3d's usage:

```
map3d
       -b -nw -nv
       -f geomfilename
         -as xmin xmax ymin ymax
         -al xmin xmax ymin ymax
         -at xmin xmax ymin ymax
         -t time-signal-number
         -c mesh colour
         -p scalar data (potentials) filename
           -s num1 num2
           -i increment
           -ph maxpotval
           -pl minpotval
           -cs contour-spacing
           -ps scaling_value
           -ch channels-filename
           -sl surfnum
         -lm landmarks-filename
         -11 leadlinks-filename
         -lh
```

4.1 Typical usage examples

Here are some typical examples of using map3d:

• Display the contents of a geometry file:

```
map3d
map3d -f geomfilename.pts
map3d -f geomfilename.fac
map3d -f geomfilename.geom
```

The first instance will run map3d and allow you to input files interactively (see Section 8.5.1).

The first form with arguments reads only the node points (.pts file extension) while the second form also reads the connectivities from a .fac file and displays both mesh and nodes. The third form assumes that a binary geometry file (.geom extension) exists that contains both nodes and connectivities. We describe all these forms of geometry files in Section 6.1.3.

• Map scalar values from a single time instant stored in a "pot" file (described in Section 6.3.1):

```
map3d -f geomfilename.fac -p datafilename.pot
```

• When there is a mapping required between the potentials and the geometry, e.g., when the order of values in the .pot and .pts file are not identical, we require a channels file (see Section 6.4 for details of the channels files),

```
map3d -f geomfilename.fac -p datafilename.pot -ch thefile.channels
```

• To display a time series of scalar values on the geometry, the basic format is the same

with the time series stored in a datafile described in Section 6.3.2.

• Geometry can also be stored in a binary file in the CVRTI format (described in Section 6.1.3). The command format is essentially unchanged

```
map3d -f geomfilename.geom -p datafilename.tsdf
```

except that channel information is usually contained in the .geom file and thus seldom needs to be specified explicitly.

• A time series data file (.tsdf) contains a sequence of potentials, as described in Section 6.3.2. To select a subset of the time series for display, append the parameters -s and, optionally, -i, for example,

```
map3d -f geomfilename.fac -p datafilename.tsdf -s 1 100 -i 2
```

to select time instants 1 to 100 with an increment between instants of 2 (i.e., 1, 3, 5, 7, ..., 99).

• Another way to describe a time series is through a series of .pot files that are numbered in sequence. For example to read a sequence of the files mapdata001.pot, mapdata002.pot, mapdata003.pot, ... mapdata009.pot

```
map3d -f geomfilename.fac -p mapdata -s 1 9
```

• Geometry files can contain more than one geometry so that we need to select a specific collection of nodes and connectivities for the display, by means of an "@" suffix to the geometry filename specification. Calling

```
map3d -f geomfilename.geom@2 -p datafilename.tsdf
```

will select geometry #2 from the file geomfilename.geom.

• Multiple instances of -f create multiple surfaces, which by default all appear in the same window. Adding the -nw option creates a separate window for each of the surfaces. So a typical call would look like

```
map3d -f geomfile1.fac -p thedata1 -f geomfile2.fac -p thedata2
```

However, you can include all the regular features for each of the surfaces so that things can get much more complex. For multi-surface displays, it is often better to use script files (see Section 5) below.

This version of map3d provides an interactive means of specifying geometry numbers from a .geom file or time instants from a time series data file (see Section 8.5.1).

4.2 Global Parameters

The following general parameters affect the entire display:

- -b = open each individual window without borders placed within a master window that still has the usual borders. To move or resize individual windows, hold the Alt (meta) key and use the left and middle mouse buttons, respectively. Most of these can be anywhere on the command line. Also, if you use -b without any other arguments, map3d will allow you to select the files interactively and add them to this master window.
- -v = show current version of the program. If this is the only argument, the program will exit.
- -nw =for multiple surfaces (*i.e.*, more than one set of points and triangles), place each surface data in a new window. By default, map3d opens a single window for all surfaces.
- -nv = to NOT check validity of geometry files. This can have a large impact on startup performance if map3d needs to load large geometries.
- -c default_mesh_colour = colour index to use on all surfaces for which there is no specific colour specification. This option must be set before any surfaces are read, since the same option sets the colors for individual surfaces.
- -dp datafile_pathname = directs the search for data files accessed to another directory. Using an alternate pathname, you can override the original directory specification for the files and get them from, say, an optical disk. This value can also be set with an environmental variable called MAP3D_DATAPATH, which you can set at any time before executing map3d. With this option, map3d looks in datapath/filename.

4.3 Geometry specifications

The basis for display in map3d is one or more geometry descriptions, which are usually in the form of surfaces, but can also be a set of line segments or tetrahedra; hence we can picture each set of nodes and connectivities as a "meta-surface", which we generally refer to as a "surface". For each such surface, map3d needs the set of node locations in three-dimensional space and usually some connectivity information that defines the (meta) surface. The geometries must exist in discrete form and be stored in files that map3d can read (see Section 6.1.3 for details of the file formats). There is no provision at present for analytically defined geometries.

To tell map3d where to look for this geometry information, each occurrence of $\neg f$ in the command line indicates that beginning of a new surface. All parameters (except for global options) that follow before the next occurrence of $\neg f$ refer to the current surface.

- -f geometry-file = filename of the geometry file(s) containing points and connectivity information. Legal formats for the file specification are:
 - 1. nodes (.pts) file will read and display only the nodes from the geometry; no display of the potentials is possible with just this information;
 - 2. triangles/tetrahedra (.fac/.tetra) file will read **both** the connectivities and the nodes (provided both exist and share the same root filename);
 - 3. binary geometry (.geom) file contains both nodes and connectivity information and may also contain channel mapping. At present, multi-surface geometry files must include a specific indication of the desired surface (@surfnum); otherwise, map3d reads all surfaces in the file.

Note: by specifying a root filename without any extension, map3d will look for all valid geometry files and try and construct the most comprehensive set. (It will do the same for data files as well.) Where there are multiple, potentially conflicting files with the same root, e.g., file.pts and file.geom, map3d will select binary over text files. See Section 6.2 for more details on the rules for specifying and reading geometry files.

- -w = place this and subsequent surfaces in a new window. This option will do nothing if the -nw option is set or if this is the first surface
- -c colour = desired colour for the mesh of a particular surface, specified as a red, green, and blue value triplet ranging from 0 to 255. Some examples are:

$255 \ 0 \ 0$	red
$0\ 255\ 0$	green
$0\ 0\ 255$	blue
$255\ 255\ 0$	yellow
$255\ 0\ 255$	magenta
$0\ 255\ 255$	cyan
255 255 255	white

- -as xmin xmax ymin ymax = set the absolute location in pixels of the surface window most recently defined. We assume an origin in the lower left corner of the screen and the typical full screen of an SGI workstation with a 19-inch monitor has 1280 by 1024 pixels. This option is useful for setting consistent layout of windows, especially when there are multiple surfaces, each in its own window.
- -al xmin xmax ymin ymax = set the absolute location in pixels of the surface window most recently defined's colormap legend window. There will be one of these windows per surface only if a valid data file is associated with it.
- -lh = Set the most recently defined surface's colormap legend window to have a horizontal instead of vertical layout.
- -lm landmark_filename = read from the file landmark_filename a set of coronary arteries, or any other landmark information stored as a series of points, with a radius associated with each. See section 6.5 below for details.
- -11 leadlinks-filename = file in leadlinks format containing a list of the node locations that correspond to a subset of the leads, e.g., the lead locations on the torso surface that correspond to the standard ECG leads. The point of identifying such leads is to display them with their own markings, either as spheres or with the lead number (typically not the same as the node number). For more information, see the menu options in Section 8.2.3 that determine the form of the display markings and Section 6.4 for more information on leadlinks files.

4.4 Scalar Data parameters

To display scalar data values on the geometry, we must specify the source of the data and how to link them to the geometry. As with the geometry, all arguments specified between two occurrences of -f in the command line refer to the currently valid surface. Within pairs of -f options, there can be only a single instance of any of the following options:

- -p potfilename = base filename for the potential and current data files. For pot files (see Section 6.3.1 for details of the format), if the -s option is used, map3d will append a number and the extensions .pot to this base filename (see -s option). For binary time series (.tsdf) files, the -s option specifies the start and end frame numbers to be read from the file. With no -s option, map3d searches for a single .pot file named potfilename.pot or for a time series file named potfilename.tsdf and will read in all time instants from the file. Note also that if you omit the extension, as with geometry files, it will try to match a .pot or .tsdf extension for you.
- -s num1 num2 = range of frame numbers to read. If we are reading data from .pot or .grad files, map3d appends each of the numbers between num1 and num2 to the value of potfilename to make complete pot filenames.
 - eg., -p good-map -s 1 3 expands to:
 good-map001.pot good-map002.pot good-map003.pot

If we are reading from a time series (.tsdf) data file, map3d will read frames num1 to num2 from the file.

- -i increment = difference between each frame number (initially). Regardless of how the data file(s) are read in, all frames are read in (or if the -s option is specified, all frames between the two points are read in). This enables the user to change the interval between frames while map3d is running.
- -ph maxpotval = maximum data value in "user" scaling mode. This sets one option for setting the range used in scaling the data value to colours and contours. You can select other ranges from the menu and can select this one again with Scaling-; Range-; Command-line specified range.
- -pl minpotval = minimum data value in "user" scaling mode.
- -cs contour-spacing = spacing between contours set by the user. This provides a menu option for selecting contours by setting a constant spacing rather than deriving the spacing from the desired number of contours and the range of data values. Note that the spacing will not always be a the command-line set value map3d will divide the range by the specified value and set the number of contours as that number, and then determine the contour values by using that number of contours with the currently- selected scaling function. You can select other numbers of contours from the menu and can select this again with Contours-; Number of Contours-; Command-line spacing
- -ps scaleval = scaling value by which map3d multiplies each potential value as it reads from the file(s). This option tries to make use of any unit information available in a time series data file and alters the unit value available to map3d for display. The resulting scaling of the data is permanent for the current instance of map3d.
- -ch channels-filename = file in *channels* format containing an entry for each node in the geometry which points to the associated location in the data array. The value of this pointer is also the number that is written next to node locations when channel numbers are displayed. See section 6.4 for more information on the channels file format.
- -lm landmarks-filename = file in landmarks format containing a set of landmark segments, divided into categories. Each category has a word depicting the landmark type. Each lines within the categories contains three points (x,y,z) and an associated radius, which may have a different effect based on the type of landmark.
- -sl surfnum = surface number to which the scaling for this surface is to be slaved. The idea here is to have surfaces locked in the way they scale and display the data; in this way, one can compare colors across surfaces to determine relative values of the local scalar data.
- -t timesignal-lead-number = number of the node to be used for the display of a time signal in its own window. The number refers to either a node number in the geometry or, if a leadlinks file is present, the *lead* number. This command is optionally used in conjunction with the -at command, to specify a node and place its window accordingly. If the -at option is not present, map3d will choose a default window location. Multiple invocations of this option are possible for each surface, providing the option to open several windows per surface. At any time during the operation of the map3d the user can select a new node via the pick mode menu item and have the time signal from that node displayed (see Section 8.6 for details).
- -at xmin xmax ymin ymax = set the absolute location in pixels of a time signal window associated with the current surface. As with the -as option, the origin is in the lower left corner of the screen and the full screen resolution of an SGI screen with 19-inch monitor typically supports 1280 by 1024 pixels. This command is optionally used in conjunction with the -t command, to specify a node and place its window accordingly. If the -t option is not present, map3d will choose a default node (the first node in the geometry). Multiple invocations of this option are possible for each surface, providing the option to open several windows per surface.

CVRTI/SCI Manual: map3d

5 Script Files

Using script files to control map3d has numerous advantages, for example:

- 1. complex layouts and specifications can be created and then held for later reuse,
- 2. execution of the program reduces to a single word that starts the script,
- 3. scripts are shell programs and can include logic and computation steps that automate the execution of the program; the user can even interact with the script and control one script to execute many different actions.

5.1 What are script files?

A script files are simple programs written in the language of the Unix shell. There are actually several languages, one for each type of shell, and the user is free to select. At the CVRTI we have decided to use the Bourne shell for script programming (and the Korn shell for interactive use) and so all scripts will assume the associate language conventions. The shell script language is much simpler to use and learn than a complete, general purpose language such as C or Fortran, but is very well suited to executing Unix commands; in fact, the script files consist mostly of lists of commands as you might enter them at the Unix prompt. Even more simply, a script file can consist of nothing more than the list of commands you would need to type to execute the same task from the system prompt.

5.2 How to make script files

Script files are simple text files and so are usually created with an editor such as emacs. You can, however, also generate a script file from a program, or even another script. But all script files can be read and edited by emacs and this is the way most are composed.

To learn about the full range of possibilities in script files requires some study of a book such as "Unix Shell Programming" by Kochan and Wood but the skills needed to make map3d script files are much more modest; any book on Unix will contain enough information for this. The instructions and examples below may be enough for many users.

Here are some rules and tips that apply to script files:

Use a new line for each command This is not a requirement but makes for simpler files that are easier to read and edit. If the command is longer than one line, then use a continuation character ", e.g., backslash

```
map3d -f geomfilename.fac \
    -p potfilename.data \
    -cl channelsfilename
```

Make sure that there are no characters (even blank spaces) after the continuation character!!! This has to be the most frequent error when the script file fails to run or stops abruptly.

Make script files executable Script files can be executed by typing . scriptfile but the simplest thing is to make then executable files so that they work simply by typing their names. To do this, use the chmod command as follows:

```
chmod 755 script_filename
```

Use the .sh extension for scripts This convention makes it easy to recognize shell scripts as such, but also invokes some editor help when you edit the file in emacs. The mode will switch to shell (much like Fortran or C mode when editing programs with .f and .c extensions) and has some automatic tabbing and layout tools that can be helpful.

Variables in scripts The shell script is a language and like any computer language there are variables. To define a variable, simply use it and equate it to a value, *e.g.*,

```
varname=2
varname="some text"
varname=a_name
```

Do not leave any spaces around the "=" sign or the command will fail and set the variable to an empty string.

Once defined, the variables can be used elsewhere in the script as follows:

```
geomdir=/u/macleod/torso/geom
geomfile=datorso.fac
datafile=dipole.data
map3d -f ${geomdir}/${geomfile} -p $datafile
```

The curly braces are required when the variable name is concatenated with other text of variable names but is optional otherwise. To concatenate text and variables you simply write them together (e.g., geomdir/geomfile.pts concatenates the two variables with a "/" and the extension ".pts".

Environment variables in scripts All the environment variables are available and can be set in the script. For example:

```
mydir=${HOME}
```

sets the variable \$mydir equal to the user's home directory. Likewise,

```
MAP3D_DATAPATH=/scratch/bt2feb93/export MAP3D_DATAPATH
```

defines and "exports" the environment variable used by map3d to find .pak files.

5.3 Examples

Below are some sample scripts, from simple, to fairly complex:

Set the geometry, data, and window size and location

```
map3d -f ${HOME}/torso/geom/dal/daltorso.fac \
    -as 100 500 300 700 \
    -p ${HOME}/maprodxn/andy3/10feb95/data/cooling.data \
    -s 1 1000
```

map3d-tank1.sh, included with this distribution

```
MAP3D=../map3d
GEOM=../geom/tank
DATA=../data/tank

$MAP3D -nw -f ${GEOM}/25feb97_sock.fac \
    -p ${DATA}/cool1-atdr_new.data@1 -s 1 1000 \
    -ch ${GEOM}/sock128.channels \
    -f ${GEOM}/25feb97_sock_closed.geom \
    -p ${DATA}/cool1-atdr_new.data@2 -s 1 1000 \
    -ch ${GEOM}/sock128.channels
```

map3d-tank2.sh, included with this distribution

map3d-torso1.sh, included with this distribution

```
MAP3D=../map3d
GEOM=../geom/torso
DATA=../data/torso

$MAP3D -f ${GEOM}/daltorso.geom -p ${DATA}/dipole2.data -s 1 6
```

map3d-torso2.sh, included with this distribution

Set some environment variables, then layout the whole display

CVRTI/SCI Manual: map3d

```
-f $basedir/geom/525sock.geom \
-as 476 800 611 935 \
-at 476 800 485 610 -t 237 \
-p $basedir/data/pace-center.data@1 \
-s 65 380 \
-f $basedir/geom/525sock.geom \
-as 150 475 176 500 \
-at 150 475 50 175 -t 237 \
-p $basedir/data/pace-center.data@1 \
-s 65 380 \
-f $basedir/geom/525sock.geom \
-as 476 800 176 500 \
-at 476 800 50 175 -t 237 \
-p $basedir/data/pace-center.data@1 \
-s 65 380
```

6 Input files

In this section, we describe the contents and formats of all the input files that map3d uses to get geometry, data, and much more.

6.1 Geometry input files

The input of geometric data may occur via a family of simple ASCII files used to describe geometry. These include the points or nodes of the geometry—stored in a file with the extension .pts—and the connectivities that described polygonal links between nodes—stored as line segments (.seg files), triangles (.fac files), and tetrahedra (.tetra files). To satisfy a need for more comprehensive and compact storage of geometry information, we have developed a binary file format and created the *graphicsio* library to manage these files. Below, we describe each of these files and how map3d uses them.

6.1.1 Points (.pts) file

The characteristics of a .pts file are as follows:

- 1. ASCII file, no special characters permitted;
- 2. Each line contains one triplet, ordered as x, y, and z values; one or more spaces between values, which are assumed to be real, floating point numbers;
- 3. Each line may also optionally contain a group number as a fourth element (although at present, map3d does not use this group information);
- 4. the order of points in the file is the implicit order of the nodes in the geometry; connectivities are based on this ordering.

6.1.2 Triangle (.fac) files

The characteristics of a .fac file are as follows:

- 1. ASCII file, no special characters permitted;
- 2. Each line contains a triplet of integer values pointing to the nodes of the geometry. **Node numbers** begin at 1 not 0!;
- 3. The order of triangle vertices (nodes) is not strictly controlled, however, it is recommended that order reflect a common convention in graphics—a counterclockwise sequence of vertices when viewed from the **outside** of the triangle;
- 4. Each line may contain an optional fourth values which is the group number for the triangle (not used by map3d);
- 5. Order of triangles in the file is not meaningful except for internal bookkeeping; user will notice ordering only when a triangle is picked for interrogation.

6.1.3 Binary (.geom) geometry files

At the CVRTI we have developed a binary file system for efficient storage of complex geometry and associated attributes, a part of the *graphicsio* library. Extensive documentation of this format is available from Rob MacLeod (macleod@cvrti.utah.edu) (www.cvrti.utah.edu/~macleod/docs) and from the CVRTI web site under the heading *graphicsio* library at www.cvrti.utah.edu/computing.shtml.

Briefly, each graphicsio geometry file contains one or more sets of node locations and, optionally, connectivities for polygonal elements composed from those nodes. It is possible in graphicsio files to associate scalar, vector, and tensor values to nodes or elements, the most relevant example of which are channel pointers, stored as a set of scalar values associated with the nodes of the geometry. Each graphicsio geometry file can contain any number of sets of geometries, each with different nodes and connectivities.

map3d is capable of reading surface geometry from either single surfaces or from all surfaces contained in a multi-surface geometry file. Command line arguments controls the selection, as we describe in the next section.

6.2 Command line control of geometry files

In map3d the -f option determines in which files the geometry is to be found. Starting from the filename that follows -f, which may or may not include a file extension, the program looks for all possible candidate geometry files and queries the user for resolution of any ambiguities. Thus, with the arguments map3d -f myfile, map3d3d looks for myfile.geom, myfile.pts, myfile.fac, etc, and tries to resolve things so that a valid geometry description is found. It is possible to direct this process by typing the geometry filename with an extension according to the following rules:

CVRTI/SCI Manual: map3d

Extension	Effect	
none	look for files with the extensions .pts, .fac, .tetra, and .geom	
	and if an incompatible set are present (e.g., both .pts and	
	.geom), ask user which to take	
.pts	take only the .pts file and ignore any connectivity or .geom	
	file	
.fac	take .pts and .fac and ignore any .geom files present.	
.geom	take the .geom file and ignore any others present.	

A further way to read geometry into map3d is to use the geometry filename that can be optionally contained within the time series file (see Section 6.3) that contains the potentials. This requires that the .tsdf file be created with the geometry filename included; adding this after the fact is difficult. Note that even if a geometry filename is found in the .tsdf file, it can be overridden by the geometry file name specified in the argument list of map3d.

6.3 Scalar data files

There are two ways of storing scalar values (typically electric potential in our applications) so that map3d can recognize and read them. One is a simple ASCII file and the other a binary format developed at the CVRTI.

6.3.1 .pot files

One way to package the scalar data values that are assigned to the points in the geometry is the .pot file. In the default condition, the scalar values in the .pot files are ordered in the same way as the node points in the geometry file with simple one-to-one assignment. With a channels file, it is possible to remap this assignment, as described in Section 6.4).

The rules for .pot files are:

- 1. Each line of the files contains one scalar data value, assumed to be a real number in single precision floating point format.
- 2. The order of the values within the file must either agree with that of the associated set of nodes or a channels file must be supplied to redirect the links between potential value and nodes.
- 3. Each .pot file *must* end with a blank line.
- 4. A single .pot file can contain only the data values associated with a single surface at a single instant in time. To represent a sequence of time steps (frames) requires a sequence of files, typically with filenames ending in a three-digit series, e.g., mapdata001.pot, mapdata002.pot, mapdata003.pot, Section 4.4 explains how to specify such a series of .pot files to map3d and Section 4.1 shows examples.
- 5. The extension .pot *must* be used.

6.3.2 CVRTI data (.tsdf) format files

The more efficient and flexible way to store scalar values is by means of the time-series data file format developed at the CVRTI, also as part of the *graphicsio* library. These files (.tsdf files) are capable of holding an entire sequence, or *time series* of scalar data in a single file, along with information about the contents, type, units, and temporal fiducials from the time series. For more details on

this file format see www.cvrti.utah.edu/~macleod/docs or the information under the *graphicsio library* at www.cvrti.utah.edu/computing.shtml.

Here are some concepts of the time series data file structure that are relevant to the different modes of operation described in this manual.

Links to geometry The links between the channels of data in the .tsdf file and the nodes of the surface[s] over which they are displayed is established via *channel* array information, which is available stored as associated scalars to the nodes in the geometry file (see Section 6.1) or in explicit channels files (see Section 6.4).

Frames By frames of data, we mean instants in the data stream representing single moments in time. For each frame, there is a set of values that for a spatial distribution or map and map3d needs to know what subset of frames are to be included in the display. To explicitly specify frame numbers, use the -s and -i options described in Section 4. As an example, the command line

```
map3d -w -f geomfile.geom@1 -p datafile.tsdf -s 10 130 -i 2
```

specifies that surface 1 from the geometry file geomfile.geom should be used to display frames 10 to 130, taking every second frame, from run 2 of the time series data file datafile.tsdf.

Time series container files: The *graphicsio* library also defines a container file format that can describe a set of time series data (.tsdf) files, and can contain parameters extracted from the associated time series. At present, map3d does not read such container files, but this will change soon...

6.4 Channels and leadlinks

6.4.1 Description of leadlinks and channels information

Channels and leadlinks files, and the arrays they contain, are identical in structure, but they have important functional differences. A run of map3d may require both, either, or neither of these, depending on the structure of the data files and geometries. The basic function of both channels and leadlinks information is to offer linkages between nodes in the geometry and the data that is to be associated with those nodes. The first file type, the channels file, links the nodes in the geometry to specific time signals in a data file; without channel mapping, the only possible assumption is that each node i in the geometry corresponds to the same time signal i in the data file. Any other linkage of geometry and data channel requires there to be channel information, typically either from a separate channels file or stored with the binary geom file as an associated scalar value for each node.

Leadlinks are purely for visualization and describe the connection between "leads", a measurement concept, with "nodes", a geometric location in space. In electrocardiography, for example, a lead is the algebraic difference between two measured potentials, one of which is the reference; "unipolar" leads have a reference composed of the sum of the limb electrode potentials. It is often useful to mark the locations of these leads on the geometry, which often contains many more nodes than there are leads. The most frequent use to date has been to mark the locations of the standard precordial ECG leads within the context of high resolution body surface mapping that uses from 32–192 electrodes. Another common application is to mark subsets of a geometry that correspond to measurement sites (values at the remaining nodes are typically the product of interpolation). In summary, leadlinks allow map3d to mark specific nodes that may have special meaning to the observer.

Figure 1 shows an example of lead and channels information and their effect on map3d. See the figure caption for details.

map3d handles this information in the following manner:

channels The *channels* information links nodes in the geometry to individual channels or time series in the data file. For example, the data values associated with node k in the geometry are located in the data location specified by the channel array value channels(k). If channels(k) < 0, then there is no valid data for node k.

Indirections in map3d

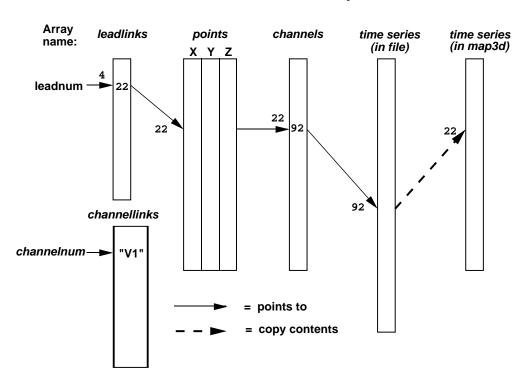

Figure 1: Example of the indirection possible in map3d through the use of leadlinks channels, and channellinks. Lead number 4 points, via the leadlinks array to node number 22. This, in turn, points via the channels array to location 92 in the multiplexed data buffer, which causes the values at time signal 92 to be loaded into location 22 in the internal data array (and displayed by map3d). In a separate, channellinks array, shown below the leadlinks array, the entry in lead 4 says that that lead should actually be labeled "V₁".

Note that map3d uses the channels arrays when loading scalar data into the internal storage arrays! Hence, the action of the channel mapping is not reversible. Should geometry nodes and data channels match one-to-one, there is no need for a channels array. It is also possible to define via a channels array the situation in which a single data channel belongs to two (or more) nodes in the geometry. The most frequent example of this occurs when three-dimensional geometries are "unwrapped" into surfaces in which what was a single edge is split and thus present at both ends of the surface.

leadlinks The *leadlinks* information is primarily used to identify and mark measurement lead specific within the geometry. The typical use is to select a subset of the nodes to identify the measurement sites—values at other sites might be interpolated or otherwise computed. Leadlinks also provide a means to renumber the labels on the nodes of the geometry in order to, for example, reproduce the numbering scheme used in an experimental setup.

In the leadlinks array each entry refers, by its location in the array, to a particular lead #; the value at that location in the array gives the number of the node in the geometry file to be associated with this lead. For example if lead 4 has a leadlinks entry of 22 (leadlinks(4) = 22), then map3d will display node 22 in the geometry as "4", not "22" whenever node marking with leads is selected).

channellinks There is an extension of the basic scheme which includes a further level of redirection for giving the leads explicit text labels. Channel links are stored as a array of strings, one for each node of the geometry. The channellinks file is organized similarly to a leadlinks file, with each line containing information for one node. However, each line consists of two values, 1) the number of the associated channel and 2) the text string to be used as the label when map3d marks the nodes with channel numbers.

Hence we have the situation of a node number K in the geometry displaying time signals from channel L in the scalar data, but labeled with string "XXX".

6.4.2 Source of leadlink and channel information

The sources of channels, leadlinks, and channellinks information are files, or parts of files, as outlined in the following paragraphs.

In .geom files Information for the *channels* array is stored as an associated scalar with the information in the standard .geom files. At present, there is no leadlinks array stored in the .geom file but this could change in the future.

In .leadlinks files A .leadlinks file is an ASCII file, the first record of which contains a line nnn leads, where nnn is the number of leads to be described in the file (and also one less than the total number of lines in the file). Each following record contains two integer values:

- 1. the first number is the number of the lead, as it should appear in any labeling of the associated node.
- 2. the second entry in each row is the value of the associated node number in the geometry.

For example, the file for a surface which reads:

indicates that there are 32 leads to be linked (the geometry can, often does, contain more than 32 nodes), and that lead #1 is called lead "1" and is node 1 in the geometry file. Lead #2 is at node 42, lead #3 is called "4" and is found at node 31. Likewise, lead #4 is called "7", and is located at node 65, and so on, up to lead #32, called "32", at node 11.

Nodes listed in a *leadlinks* file that is passed to map3d with the -ll option can be marked in a number of ways, described more fully in Table 10 in Section 8.2.3.

In .channels files A channels file is an ASCII file, the first record of which contain a line nnn nodes, where nnn is the number of nodes to be described in the file (and also one less than the total number of lines in the file). There is one line in the file for each node of the geometry to which we wish to associate scalar data. Each following record contains two integer values:

- 1. the first number is simply a running counter that indicates the node number with which to associated the second value in the row.
- 2. The second value in each row is the *channel* number for that node; a negative number signifies a node to which there is no data associated.

For example, the file for a surface which reads:

352 Nodes
1 123
2 632
. . .
22 -1
23 432
. . .
352 12

indicates that there are 352 leads to be linked, and that the data value for the first node is located at location 123 of the data file. For node 2, the data value is to be found at location 632, and so on. Node 22 does not have any scalar data associated with it.

6.4.3 Display of lead/channel information

To see how map3d can display the node and lead information, see Sections 7.7 and 8.

6.5 Landmark files

Landmark files contain information for visual cues or landmarks that map3d can draw over the surfaces in order to aid and orient the viewer. Initial use was primarily for coronary arteries, but the idea has expanded to incorporate a number of different orientation landmarks. The original coronary artery class of landmarks requires only that each can be described as a series of connected points, with a radius defined for each point. The coronary landmark is then displayed as a faceted "pipe" linearly connecting the points at the centre, with a radius, also linearly interpolated between points, determining the size of the pipe. The landmark file can contain numerous, individual segments of such pipe-work, each of which is drawn separately.

Other classes of landmarks are described below, but all of them can be described in a file with the following general format:

Line number	Contents	Comments
1	nsegs	number of landmark segments in the file
2	1 type nsegpts seglabel	segment number (1), type, number of points,
		label_number
3	X, Y, Z, radius	point location and radius of point 1
4	X, Y, Z, radius	point location and radius of point 2
•		
	<u> </u>	
nsegpts + 2	X, Y, Z, radius	point location and radius of last point in seg-
		ment 1
•	2 type nsegpts seglabel	segment number (2), segment type, number of
		points, and label
•	X, Y, Z, radius	point location and radius of point 1
	X, Y, Z, radius	point location and radius of point 2
•		•
•	i	
•	X, Y, Z, radius	point location and radius of last point in seg-
		ment 2
	•	
	•	
	•	•

The landmark types defined to date are the following:

Name	Graph. object	Description
Artery	faceted pipe	a coronary artery/vein segment
Occlusion	coloured sphere	an experimental occlusion that could be open and
		closed
Closure	coloured sphere	a permanent occlusion that cannot be opened
Stimulus	coloured sphere	a stimulus site
Lead	coloured sphere	a particular electrode or lead location
Plane	rectangular parallolop-	a visible (but not functional) cutting plane through
	iped	the geometry (Note: do not confuse this with the cut-
		ting planes that $map3d$ provides for slicing through
		the geometry).
Rod	lines	rod inserted into needle track to digitize needle elec-
		trode locations.
PaceNeedle	sphere	location of a pacing needle entry point
Cath	faceted pipe	location of catheter in a vessel
Fiber	arrow	local fiber direction indicator
RecNeedle	sphere	location of recording needle entry point
Cannula	tube	coronary vessel cannulus

Specifying snare, closure, and stimulus requires a single point in the landmarks file, and the resulting sphere is coloured according to a set of values defined in the drawsurflmarks.c routine. At present, the values used are:

Occlusion	cyan
Closure	blue
Stimulus	yellow

and they are not (yet) adjustable by the user, except by using the "regular" trick of playing interactively with the colour map with the cedit program (only works with older versions of map3dGL).

To specify a plane landmark requires three "points"

Point	X,Y,Z	Radius
1	First point of plane	Radius of the plane
2	Second point of plane	Thickness of the plane
3	Third point of plane	not used

The plane is drawn as a polygon with the number of sides controlled by a program variable.

Filename conventions: The standard extension of a landmark file is .lmarks and the filename is specified by the -lm parameter for each surface.

Control of landmark display: for details of how to control the display of landmarks, see Section 8.7.

7 Display features

This section describes the displays that map3d generates and what they mean; for specific information on how to control map3d and the displays, see Section 8.

7.1 Multiple surfaces

The idea of map3d has always been to display multiple sets of data on multiple surfaces; the limitation has been how much flexibility to include in a single invocation of the program. This version of map3d, as opposed to previous versions, can now handle multiple windows each with multiple surfaces. Surfaces can be moved between windows (see Section 8.5.1) When map3d displays multiple surfaces, each can exist in its own full window with its own border and window title bar, or, map3d can build a single main window with multiple sub-windows inside the main window. The user can reposition and resize each of these sub-windows using the Alt(Meta) key and the left and middle mouse buttons respectively. To create this layout of main window and frameless sub-windows, use the -b (borderless windows) option when launching map3d as described in Section 4.3.

7.2 Surface display

The basic forms of display of the surfaces are

- nodes or points from each surface
- connectivity mesh
- shaded surfaces based on either the geometry or the associated scalar values, with a number of different rendering options.
- landmarks superimposed on the surface display

7.3 Mesh Rendering

Often the purpose of map3d is to render a geometry consisting of nodes and connectivities and there are several basic modes of rendering this information.

Points: display just the nodes of the geometry as dots or marked with spheres.

Connectivities: display the connectivity information for the mesh as lines joining the nodes.

Elements: treat each polygon in the mesh as an element and render it in a way that shows its surface; for triangles, simple render each triangle surface; for tetrahedra there is no specific rendering in this version of map3d.

Elements and connectivities: map3d also supports a hybrid mode of rendering that shows outward facing triangles (using the convention of counterclockwise ordering) as elements but backwards facing triangles as connectivities.

map3d also has the ability to render all elements with a lighting model. This is especially useful for displaying the elements of the mesh. Additional controls to note are depth cueing, which can reveal the depth relationships between elements of the mesh.

7.4 Surface Data Display

The main use of map3d is to display scalar data associated with geometry and there are numerous options and controls to facilitate this. The two basic ways of conveying scalar value information are as shaded surfaces and contour lines and map3d supports each separately, as well as in combination. For surface shading, there are several basic rendering modes:

Flat: each triangle received a single color that depends on the mean value of the scalar value over that triangle.

Gouraud: the colour of each triangle values linearly with the value at each of the vertices

Banded: the regions between contour lines have a constant color, even if the contour lines are not visible.

Contours: this can be a separate rendering mode, or combined with any of the three modes above. Contours are lines that trace iso-values over the surface of the geometry.

7.4.1 Data scaling

There is a wide variety of options available for mapping scalar values to colour and contour levels. One can picture the process as based on four facets:

Extrema: the extrema of the data and the selected colour maps determine the basic parameters of how value maps to color. map3d maintains a detailed list of data extrema organized both by time signal, time instant and by surface. Thus it is possible to determine extrema based on just the most local of conditions—a particular frame and surface—or by more global conditions—the full range of frames or the full set of surfaces.

Scaling function: the mapping between value and color occurs according to some mathematical function, the simplest of which is linear. The scaling function uses the selected extrema and describes a complete mapping between value and color.

Mapping: by scale mapping, we mean how the translation from value to color treats positive and negative values. We may choose to map uniformly between the extrema or to apply different extrema or functions to the positive and negative values.

Color maps: the color displayed for a particular scalar value depends on the actual range of colors and their order in the color map.

map3d can adjust all four facets of the scaling to create a wide range of displays. We chose to limit some of these options, however, in an effort to create reproducible displays that reflect standard within the field. Of course, we chose our field, electrocardiography, as the basis, a fact for which we make no apologies and simply encourage others to make similar choices for their own field and implement map3d accordingly. Subsequent versions of map3d will support this flexibility.

Below are the specific choices that map3d offers to control data scaling and display

Scale range map3d supports several selections of range over which to look for extrema. In local range, only the data presently visible are scanned for extrema—this is the default. In the full global range, all the data in the entire dataset are used, even those not presently visible on the display. In between these cases, one can have global in time and local in space, i.e., we scale each surface separately but use all time values for that surface. Or one can select local in time and global in space, in which map3d scans all surfaces for the data extrema, but for each time instant separately The user scaling scope uses the current user-selected values for maximum and minimum for the scaling (see -pl and -ph input parameters in Section 4). The user can also select group scaling, where he assigns surfaces to groups and the range is based on the group min/max (either local in time or global). Groups are assigned by the menu. The user can also do slave scaling, where he assigns one surface (slave) to another's (master) range. The slave surfaces are currently only set through the command line, by placing a -sl num (where num is the surface number of the master) after declaring the slave surface. See Section 8.2.3 and Section 'refsec:scalarparams for details.

Scale function The scale model describes the way in which scalar data are mapped to colours (or contours). The present choice is linear, but the next version of map3d will include: **linear** model, which simply maps the data to a range of colours in a completely linear fashion, *i.e.*, $colour = K\phi$; the **logarithmic** model, which highlights the lower level data values at the cost of poorer resolution at the higher levels *i.e.*, $colour = A \log(\phi) + B$; and the **exponential** model, which does the opposite,

compressing the smaller levels and expanding the higher ones to span a wider colour range, i.e., $colour = Ae^{B\phi}$.

The two schemes with fixed numbers of contours, log/7-levels and log/13-levels both map the upper decade (ϕ_{max} to $\phi_{max}/10$.) of the potential data range into a fixed set of logarithmically spaced values. These values are composed of a mantissa from the standard E6 (1.0, 1.5, 2.2, 3.3, 4.7, 6.8, and 10.) and E12 (1.0, 1.2, 1.5, 1.8, 2.2, 2.7, 3.3, 3.9, 4.7, 5.6, 6.8, 8.2, and 10.) number series, and an exponent such that the largest mantissa falls into the range 1.0 to 10. Hence as long as the extrema is known, it is possible to read absolute values from the individual contour lines.

Scale Mapping There are several different ways to manage the way positive and negative data are treated in the scaling transformations in map3d. The current version supports the simplest, or true mapping, in which the data are used as they are with no consideration of positive or negative values—the color map spreads evenly across the range of the extrema. Subsequent versions will support the symmetric scale mapping, which sets the positive and negative extrema symmetrically—the larger (in the absolute value sense) determines both maximum and minimum data values. Also to appear in the net version is the separate scale mapping, in which the positive and negative extrema are treated completely separately—'half' the colours (and contours) are used for the positive values, half for the negative values. This is equivalent to producing maps with the same number of contours for both positive and negative values, even when the positive data have a different absolute maximum value than the negative data.

Colour Map There are four different colour maps presently implemented with every chance of more to come. The user can select which colour map to use. The choices currently implemented are:

Rainbow map Colours range in rainbow fashion from dark blue (for negative extrema) through greens (near zero) to red (positive extrema).

Red (+) to Green (-) Largest negative value is coloured bright green, dark grays are for the region near zero, and positive values appear red.

Black (+) to White(-) Grey shades from black for small values to white for large ones.

Note that for each color map, the direction of the mapping to value can be inverted, e.g., in the default directions, blue indicates small or negative values and red indicates large or positive values. Inverted, this map uses red for small values and blue for large values.

Contour spacing the contour values are a function of the data and the user selection of scale range, model, and mapping (see following items). Fundamentally, the user selects between contour spacing based on the number of contours selected or based on fixed spacing between contours. The actual result depends, in turn, on the range of data values and the desired mapping between value and colour.

7.5 Landmarks

Landmarks provide a means to include visual icons and markers in the surface display in map3d. They are not meant to render realistically but simply to be cues to assist the user in identifying perspective or features of the surfaces. The list of support landmarks reflects our current usage for bioelectric field data from the heart but many of the landmark types are general purpose and hence useful in other contexts.

Section 6.5 describes the currently support landmark types and the files that contain them. Display of each landmark type depends on the type and user controlled options (see Section 8 for details on controlling the display).

7.6 Clipping Planes

Clipping planes allow you to remove from view certain parts of the display so that you can better see what is left. So everything on one side of the clipping plane is visible and everything on the other is not.

We have two clipping planes in map3d and their position and alignments are adjustable as well as their relation to each other—we can lock the clipping planes together so they work like a data slicer, always showing a slice of constant thickness.

The controls for clipping planes are adjustable from the menus (see Section 8.2.3) and also via keyboard controls (see Section 8.2.2. The basic controls turn the two clipping planes on and off, lock them together, and lock their position relative to the objects in the surface display. By unlocking the last control, you can select that part of the display you want to clip; the default clipping planes are along the z-axis of the object (up and down). To control position of the planes along their normal direction, just keep hitting the bracket keys (\parallel and $\{\}$).

7.7 Node marking

Node markings are just additional information added to the display of the nodes. This may be as simple as drawing spheres at the nodes to make them more visible, or as elaborate as marking each node with its associated scalar data value. Section 8.2.3 describes these options in detail.

7.8 Time signal display

Display option for the time signal are very modest in this version of map3d. This will change...

Figure 2 shows the layout and labeling of the scalar window. Font sizes adjust with the window size and the type of units may be explicit if the time series data (.tsdf) files contain this information.

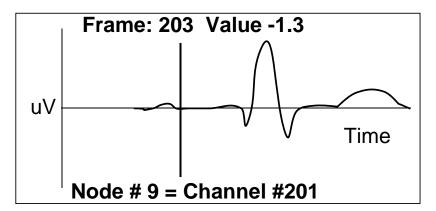

Figure 2: Time signal window layout. Vertical line indicates the frame currently displayed in the surface plot. Text annotations can vary with the data content and mode settings.

For directions on how to control the time signal window, see Section 8.3.

8 Control of map3d

This section describes all the means of controlling the function of map3d, at least all the ones we are willing to tell you about.

8.1 Control by surface

There is an ever growing number of parameters that the user can alter for displaying the surfaces in map3d. Some of the more important (and stable) include the following:

Visibility: of points, mesh, potentials, vectors, *etc*, can all be controlled individually by using the appropriate function key (see Section 8.2.2),

Lead markings: of the nodes in the geometry according to their node number, channel number, lead number or even value,

Scaling: scaling of value to colour and to contour line values,

Landmarks: appearance of the landmarks on the surface.

Since this level of control is provided for each surface, it is possible to have points showing on one surface, mesh on another, and rendered potential shading on a third, and so on.

8.1.1 Selecting which surface to control

To control the display of each surface, be that a surface in its own window or sharing a single window with other surfaces, a user must select that surface. Otherwise, display options will affect all the surfaces. There are two different multi-surface situations and each has its own method of selecting the surface:

Selecting surfaces for display controls		
Multi-surface layout	Selection method	
One surface per window	Mouse location establishes currently active	
Several surfaces in one window	window. Up/down arrows selects the surface. Hitting the up-arrow key after selecting the last surface selects all surface.	

Note that in the surface window, the lock icons in the lower left corner indicate if parameter settings act on all surface (locks visible) or just single surfaces (locks invisible). Each lock controls a different aspect of map3d:

General Lock: is represented by the yellow (or first) lock icon. When this lock is active, menu items and keyboard commands pertain to all surfaces. To turn this lock off and on use the up and down arrow keys.

Transformation Lock: is represented by the red (or second) lock icon. When this lock is active, rotation and translation pertain to all surfaces. To turn this lock on and off, use the "t" key.

Frame Lock: is represented by the blue (or third) lock icon. When this lock is active, frame advancing, retreating, and resetting pertain to all surfaces. To turn this lock on and off, use the "f" key or select from the menu under *Frame Controls*.

Note: in the case where all surfaces are in the same window, unlocking the general lock by means of the up or down arrow keys selects the single surface to display. However, when the general lock is active and either of the other locks is disabled, the active surface mesh appears in a different color (blue by default). This identifies the selected surface and all modifications apply to this surface. To select the desired surface use the (/) keys; "(" selects the next surface and ")" selects the previous.

8.2 Mouse control, keyboard mapping, dials, and menus

Direct interactive control of map3d is by the keyboard and mouse. Many option are available via the menus controlled with the right mouse button, while others can be activated or toggled with single keystrokes. Variable (non-binary) adjustments usually occur through dialogues, or by repeating keystrokes. Below are tables of all the current control devices and their function. When the program launches, the user sets one or more windows which can be resized and moved at any time. When launching the program with the -b option, the resulting borderless sub-window(s) can still be moved and resized within a main window using the Alt-key together with the left and middle mouse buttons respectively.

CVRTI/SCI Manual: map3d

8.2.1 Mouse control

The mouse can be used for different purposes depending on the current mode. This is especially important when picking is selected. To shift between modes requires simultaneous pressing of the various modifier keys, shift, control, alt. Figure 3 shows the various actions of the mouse buttons.

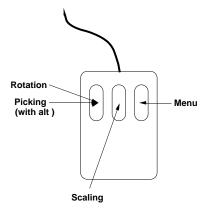

Figure 3: Mouse action for map3d. Picking makes intensive use of the mouse, as does moving objects in the surface window.

In surface windows: when the mouse is over a surface window, mouse buttons have the following actions:

Mouse Actions		
Control Key	Button	Action
None	Left	rotation objects
	Middle	scale objects (downwards increases size, up-
		wards decreases size)
	Right	activate pull-down menu
Cntrl	Left	pick a node (and if time series data is present,
		select the channel to display in the time series
		window)
	Middle	no action
	Right	no action
Shift	Left	translate objects
	Middle	scale objects (rotates clipping planes if they
		are active - more info later)
	Right	no action

In borderless windows: when the mouse is over a surface within a borderless main window (-b option), the buttons have the following additional actions:

0	6
0	•

Mouse Actions		
Control Key		Action
Alt	Left	Move a single surface subwindow
	Middle	Resize single surface subwindow (no indica-
		tion of change until release of mouse button).
	Right	no action

Note: if map3d does not respond as described in these tables, it could be that your window manager is grabbing the mouse/key combinations for its own purpose or maps the keys a little differently. This will require some setting changes for the window manager. To make such changes under IRIX, examine the .4Dwmrc file; in Linux there is usually a control panel or utility application to manage all window system interactions.

8.2.2 Keyboard controls

Each key of the regular keyboard, the function keys, and the keypad may be mapped to some function of the map3d. Some keyboard keys serve as toggles to change between a mode being on or off, e.g., "n" toggles the display of node markings. Others cycle through a set of choices, e.q., "m" runs through a series of display options for the mesh. A list of the keyboard keys and their functions is shown in table 1 and table 2 describes the action for each of the function and arrow keys, and table 3 the actions of the keypad keys. The keys affect action only in the Geometry Window unless otherwise specified.

8.2.3 Menu layout

Access to the menus is by means of the right mouse button, as per the usual OpenGL convention. Below is a series of tables of the menu layout for map3d's Geometry Window.

Following are the controls for the menus of the Time Signal Window, Legend Window, and Main Window, respectively.

8.3 Controlling the time signal window

There are two ways to create a time signal window:

- 1. Specify a -at xmin xmin ymin ymax on the command line (optionally with trace-lead-number to specify the channel to use).
- 2. Using picking to select a lead to show in the time signal window, when the current pick mode is time signal new-window mode or time signal refresh mode. Note that subsequent time signal picking can be set to either a) update the last time signal window to the new data channel or b) add yet another time signal window.

The format of the scalar display is fairly simple, with a vertical bar moving along the time axis as the frame number is advanced. map3d derives the time axis label from the frame numbers of the signal relative to the time series data file, not relative to the subset of frame read in, i.e., if frames (or pot file numbers) 10–20 are read in with an increment of 2, then frame number will begin at 10, and go through 12, 14, 16, 18 and end at 20 rather then beginning at 0 or 1 and going to 10 (the number of frames of data actually read).

8.3.1 Adjusting the frame marker

In order to facilitate rapid movement through large datasets, the user can control the frame number being displayed by interacting with the scalar window itself. If the user moves the cursor to the scalar window and pushes the left mouse button, the vertical time bar will jump to the nearest sample to the cursor location. The user can then hold the left button down and slide the time marker left and right and set a desired frame. Once the mouse button is released, map3d updates the map display. The left and right arrow keys also shift the frame marker back and forth. The only other command allowed when the cursor is within the scalar window is the "q"-key, to shut down just the scalar window, the "f" key, to toggle the frame lock, or the "p" key, to toggle the display mode. Any other attempt at input will not be accepted.

0	6
~	-

	Regular keyboard	
a/A-key	Switch colour tables	
c-key	Toggle contour draw	
d-key	Toggle depth cueing	
f-key	Toggle frame lock (also in Time signal window)	
i-key	Toggle "direction" (invert) of color table	
l-key	Toggle use of lighting	
m/M-key	Step through mesh/node drawing options	
n-key	Toggle display of node labels (some node marking must be selected)	
p-key	Toggle information in time signal (pick) window (also in Time Signal Window)	
q-key	Quit or destroy a sub-window - Legend Window and Time Signal Window only (Escape quits the whole program)	
r-key	Reset to startup conditions	
R-key	Reset shading model (to wireframe rendering)	
s/S-key	Cycle through the various surface data draw options	
t-key	Toggle transformation lock	
x-key	Draw axis	
Escape	Quit the program, if pressed in a Geometry Window, or De-	
	stroys a Time Signal Window if pressed there.	
+/- key	Increases/Decreases size of of currently-selected object (see Section 8.4.3)	
(/) key	Changes which susrface inside a window will be affected when the general lock is on but the transform or frame lock is off (see Section 8.1.1)	
	Clipping Controls	
<-key	Toggle front clipping plane	
>-key	Toggle rear clipping plane	
[/]-key	Move front clipping plane in (initially) $+z/-z$ direction respectively	
{/}-key	Move rear clipping plane in (initially) $+z/-z$ direction respectively	
,-key	Lock/Unlock clipping plane rotation with object rotation (when unlocked, shift-Middle-click rotates clipping planes)	
key	Lock/Unlock clipping planes from each other. When active,	
· noy	clipping planes move together	

Table 1: Keyboard controls for Geometry Window in map. When control contains both lower and upper cases of a letter, one cycles through a parameter in one direction and the other in the reverse direction. Note that when clipping is active, the screen information disappears.

	Arrow Keys
Left Arrow Key	Retreat by current frame step (Also in Time Signal Window)
Right Arrow Key	Advance by current frame step (Also in Time Signal Window)
Up Arrow key	Select next surface
Down Arrow Key	Select previous surface

	(left)			
Alt-Keypad Down-Arrow	-Y-translation	Alt-Keypad Up-Arrow	+Y-translation (up)	
	(down)			
Alt-Keypad Home	-Z-translation	Alt-Keypad PgUp	+Z-translation (towards)	
	(away)			
Plus/Minus key	Increase/Decrease size of currently-selected object. (see Section 8.4.3)			

Table 3: Keypad controls in map3d - have NUM-Lock off for these to work properly. Again, based on how you have your keys mapped, you might have to use the non-keypad keys, but something should work for you for each key.

Overview of Geometry Window menus		
Surface Data	display features of the scalar data displayed on the mesh	
Scaling	links between data values and color	
Mesh	display features of the mesh	
Contours	number or spacing and display features of the contours	
Picking	selecting times signals, mesh information, or other direct in-	
	teractions with the display via the mouse	
Node marking	marking of the nodes	
Graphics	general display features such as lighting, clipping, and depth	
	cueing	
Landmarks	features for toggling and displaying landmarks	
Frame Controls	modifying frame controls	
Window Attributes	features of the windows such as color and text labels	

Table 4: The overall menu structure of the Geometry Window

8.4 Color/Size Selection

It is frequently necessary to control color and size of elements of the map3d display and this, we have selection subwindows that appear as necessary and disappear upon selection. While the Color and Size Picker leave much to be desired aesthetically, they improve on past versions, and have slightly more functionality.

8.4.1 Color Picker

Figure 4: Color Picker.

	Surface Display Menus		
Color	Rainbow Green to red White to Black Invert	use rainbow color map to render scalar values on the mesh use green to red color map use black and white color map invert the sense of any color map, e.g., black becomes white and white becomes black	
Render style	None Flat Gouraud Banded	Turn Shading off colour each mesh element in a con- stant color according to the mean value of scalar data over the vertices shade each polygon using linear inter- polation draw the regions between contour lines as bands of constant color	
Toggle surface display	toggle display of the scalar data on the mesh (without changing other settings)		

Table 5: Submenus to control the display of scalar data on the mesh.

The Color Picker shows a number of colors to select from. There are only a limited number of colors so that the color selection can be easily reproduced on subsequent runs. When you open up the Color Picker, the current (original) color will be in a small box on the bottom left, whereas the box next to it will show the color that was most recently selected. There is a new "Preview" button which will change the color and let you see what it would do, but will also allow you to push the "Cancel" button and return to the original color, shown in the bottom left.

8.4.2 Size Picker

Figure 5: Size Picker.

The Size Picker shows 10 sizes to select from, currently (to change later) represented by the size of boxes, where the width of the box represents the selectable size. When you open up the Size Picker, the current (original) size will be represented in a box on the bottom left, whereas the box next to it will show the size that was most recently selected. There is a new "Preview" button which will change the size and let you see what it would do, but will also allow you to push the "Cancel" button and return to the original size, shown in the bottom left.

8.4.3 Interactive Size Control

Rather than having to open the Size Picker over and over, map3d provides a few options that can be changed by a single keystroke. To do this, open the menu in the Geometry Window and select "Mesh-¿Use +/- to select" and then select a feature you wish to dynamically adjust. Then press + or - to adjust the size. However, most of these only have 10 possible sizes.

	Scaling Menus		
Scaling	opens up the scaling dialog. (see Section 2)	ion 8.5.3)	
Range			
	Local	scale based on the local extrema for each sur-	
		face and time instant	
	Global over all frames in one surface	scale based on the extrema over the full times	
		series	
	Global over all surfaces in one frame	scale based on the extrema over each surface for the local time instant	
	Global over all surfaces and frames	scale based on the extrema over all surfaces	
	Global over all surfaces and frames	and all time instants	
	Scaling over groups in one frame	scale based on the extrema over each surface	
	Scaling over groups in one frame	in specified group for the local time instant	
	Scaling over groups in all frames	scale based on the extrema over each surface	
	S S	in a specified group for all time instants	
	Slave Scaling over one frame	scale based on the extrema over each surface's	
	_	master surface (set with -sl in command line)	
		for one time instant	
	Slave Scaling over all frames	scale based on the extrema over each surface's	
		master surface (set with -sl in command line)	
		for all time instants	
	Command-line specified range	scale based on the extrema set in -ph/-pl op-	
- T		tions	
Function	Lincon	linear manning between value and calen	
	Linear Logarithmic	linear mapping between value and color color changes as log(value)	
	Exponential	color changes as log(value) color changes as exp(value)	
	Lab standard	color reflects lab standard	
	Lab 13 standard	color reflects lab 3 standard	
Mapping	Day 19 buildard	COTOT TOTICOUS IND TO SUMMENT	
1.1.0771118	True	use true extrema	
	Symmetric about zero	take largest of absolute values of extrema to	
		determine scaling	
	Separate about zero	scale positive and negative portions of the	
	_	scale independently	
Grouping			
	Move to group #	Select a group to place the current surface (make sure the general (yellow) lock is off, or all surfaces will be placed in that group)	

Table 6: Menu for scaling, the mapping from data value to color for rendering.

8.5 Interactive GUIs - File Selection, File Saving, and Scaling Options

This version of map3d adds new GUI support. The most noticeable new addition is the "map3d Files" window, allows you to interactively select filenames, data windows, etc. The others are for saving files, and for quick scaling changes.

8.5.1 Files Window

The "map3d Files" window can be accessed by the "Mesh-¿Files..." menu entry. This window displays one row for each surface, where each row shows the surface number, the window the surface appears in, the geometry filename, the geometry number, the data filename, the start frame number, the end frame number, a graph of the RMS curve, and a button to show other files. Most of these columns can be modified at any time. If you click on the "New Surface" button, an empty row will pop up, allowing you

Figure 6: Files Dialog for map3d.

to add a surface from scratch.

None of the changes you make will take effect until you click on the "Apply" button. If you click on the "Close" button, the window will close, but if you open it again, it will look exactly as when you closed it.

Column description		
Surf	Number of the surface	
Win#	Number of the window that contains this surface. You can	
	change this number to move the surface to any open window,	
	or to a new window (by selecting the last number from the	
	drop-down menu.	
Geom File	Name of the geometry file of this surface. You may change the	
	geom file by clicking on the button and finding the file you	
	want in the file picking window that will appear. You may	
	reload the current geometry by selecting the "Mesh-¿Reload	
0 "	Geometry" menu entry.	
Geom#	Number of surface within the geometry file (see Section 6.1.2). If the major was the geometry file (see Section 6.1.2).	
	tion 6.1.3). If there is more than one surface in the geometry file, you may select which one you want from the drop-down	
	menu. If you change the geometry file, this menu will be	
	updated.	
Time Series File	Name of the data file of this surface. You may change the	
	data file by clicking on the button and finding the file you	
	want in the file picking window that will appear. You may	
	reload the current geometry by selecting the "Mesh-; Reload	
	Data" menu entry.	
Start Frame	Start reading data at this frame. You can also left-click in	
	the graph section and drag to select the correct frame and	
	this number will be updated.	
End Frame	Finish reading data at this frame. You can also middle-click	
	in the graph section and drag to select the correct frame and	
	this number will be updated.	
Graph	Graph of the root-mean-square deviation of each node for	
	each time instance. You can left- or middle-click in this graph	
	to select your data window, (and the number in start frame	
O.I. Ell	or end frame will update).	
Other Files	This button will pop open another window in which you can	
	view/modify the channels, leadlinks, or landmarks file to use	
	with this surface.	

Also note that this window allows you to run map3d without any arguments. If you do so, or if map3d3d determines that none of the geometry files were valid, the files window will pop up with an empty row waiting for input. If you try to close this window without any input, map3d will treat is as though you were exiting the program.

Figure 7: Other Files Dialog for map3d - Select Channels, Leadlinks, and Landmarks files

Figure 8: Empty Files Dialog. map3d will start up this way if you run without arguments.

8.5.2 Saving Files

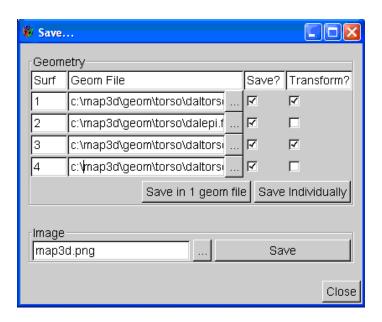

Figure 9: Saving Dialog.

The "Save..." Window will display if you select "Window Attributes-¿Save..." from the menu. The first section is to save geometry files, and the second is for images.

In the Geometry section it displays each surface number with its current geometry filename. Next to each there is a check box. If that check box is checked when you click one of the save buttons, then that surface will be one of the ones that is saved. If the second check box (labelled Transform?) is checked, then map3d will save the geometry will be saved with the current transformations (translations and rotations) applied.

Make sure to modify the filename or the current filename will be replaced (if you click on ... you can browse for a filename). If the filename ends in the extension .fac, it will save filename.fac and filename.pts. If the filename ends in .geom, it will save the file in the CVRTI binary file format (see Section 6.1.3). If Transforms is selected and there is a landmarks file, then a filename.lmark.

Clicking on the "Save in 1 geom file" button will save all of the geometry into 1 CVRTI binary file (see Section 6.1.3), choosing the filename of the first entry, which must have a .geom extension. Clicking "Save individually" will save each in its own filename. There is currently a known bug with saving .geom files under Windows and reading them back in again.

In the image section, select a filename (you can click on ... to browse for a filename) and click save. The filename may have the extension .ppm, ,png, or .jpg to save in one of those formats. The image that will save is approximately the space that all open map3d windows cover. There is currently a known bug that on X-based systems, images will not save if your default color depth is not 24 bits.

8.5.3 Scaling Options

Figure 10: The three tabs of the Scaling Dialog.

This dialog is pretty much a duplicate of the Scaling Menu in the Geometry menu, but in dialog form for convenience sake. Click on the tab at the top of the scaling type you wish to change (Range, Function, or Mapping), and click on the check box of the feature you wish to select, and map3d will update. (see Section 8.2.3, scaling menu)

8.6 Picking mode

By "picking" we mean selecting some piece of the display in the current window using the mouse (with buttons). map3d currently supports selection of nodes or triangles with different actions, all of which either return some information, affect the display, or even alter the geometry of the display. In version 5.4, the choices are limited to node information, triangle information, time signal displays, triangulation, triangle deletion, and triangle flipping. Note that picking is successful and the desired results occur only when there is one (no more, no less) hit. To aid in getting the one hit, you may adjust the picking aperture or activate the clipping planes. In any picking mode where your geometry is modified, you might want to save your geometry (see Section 8.5.2). To control picking, use the top-level "Picking" menu. See Table 9 for the available options.

8.6.1 Time Signal (new window mode)

This mode opens up a new window and provides information about the node/channel. It tells the node number, channel number, the associated surface, the current frame number, and the value of the scalar data at the current time instance. In addition, it shows a graph of the scalar data associated with that node over time.

8.6.2 Time Signal (refresh window mode)

This mode provides the same information and graph as the new window mode, but displays the information in the most-recently created window (and creates one if one doesn't exist).

8.6.3 Node Information

This mode outputs information of the selected node to the console: Surface number, frame number, node number, channel number, current data value, and the X,Y,Z coordinates of the point (as read by the geometry file).

8.6.4 Triangle Information

This mode outputs information of the selected triangle to the console: Surface number, triangle number, and the numbers and X,Y,Z coordinates of the 3 triangle points (as read by the geometry file).

8.6.5 Triangle Construction (Triangulating) and Deletion

In this mode, the left mouse is used to select the nodes that you wish connected into a triangle. Note that each time you select a valid point a change is made to the geometry. The first valid point you will see a new point on the mesh. The second will be similar except there will be a line connecting the two points, and the third time will add the completed triangle to the geometry

CVRTI/SCI Manual: map3d

Pushing CTRL-middle mouse button selects a triangle and kills it, removing it from the list.

8.6.6 Triangle flipping

Often it is necessary to know the orientation of the triangles in the geometry. While this can be computed, there remains a 180-degree ambiguity as to which way the normal points. To resolve this, triangles nodes should be ordered in a counterclockwise direction as viewed from the "outside" of the surface to which the triangle belongs. This convention is used by OpenGL to decide which triangles to show in "hide backfacing triangles" mode. Unfortunately, it is not always possible when constructing geometric models to tell which way the triangle is to be viewed—this is still something humans do better than computers—and so we often need to edit a geometric model so that the triangles are 'flipped' the right way. Hence, the "Flip triangle" option in the "Picking" menu.

8.6.7 Edit node

If your surface isn't perfect, you can edit the positions of the nodes. Select this pick mode in the Picking menu, and pick a node. A mark will appear on the node that you pick. Then use the keyboard transformation controls to translate a node (see Section 8.2.2, keypad controls). Note that keyboard rotation won't work in this mode.

8.6.8 Edit landmark point

If your landmarks aren't perfect, you can edit their positions. Select this pick mode in the Picking menu, and pick a landmark point. A mark will appear on the point that you pick. Then use the keyboard transformation controls to translate it (see Section 8.2.2, keypad controls). Note that keyboard rotation won't work in this mode.

8.6.9 Delete node

In this mode, any node you pick and any triangle that connects with it will be removed from the geometry.

8.7 Control of landmark display

There are some lighting and colour controls for the display of landmarks that are useful to know about. Table 12 describes all the specific menus mentioned here.

- Coronary/Catheter: these are controls to adjust color and visibility of the vessel type landmark, the ones we use for arteries and also for catheters. You can also switch from a rendered version of this landmark type to a wire mesh that is labeled according to segment numbers—a debugging tool when the vessels are not going where you expect.
- **Points:** there are a range of point types in the landmark suite and this option allows you to control them turn them off and on, adjust color, etc.
- **Planes:** for the plane landmark, you can set color, but also the transparency level of the plane. Default is transparent and this usually works best.
- **Rods:** as with points, there are different rod type landmarks and with this menu you can control their visibility and color.
- **Toggle all landmarks:** this is the master switch and toggling it turns all the landmarks from on to off or vice versa.

Pic	cking Menus
Time Signal (new window mode)	create a new time signal window with each
	pick of a node
Time Signal (refresh window mode)	update the last time signal window with each
D. 1	pick of a node
Display node info mode	Picking will cause certain node information to
Dignlay triangle info mode	be dumped to the console.
Display triangle info mode	Picking will cause information about the triangle you click in to be dumped to the console.
	It may be easier to pick triangles with clipping
	planes on.
Triangle construction/deletion	Normal picking (ctrl-clicking on nodes) will
,	select points to form a triangle (triangulate).
	Clicking the first two nodes in this fashion will
	display the selected nodes, and then a line be-
	tween the two. When the third is clicked, a
	new triangle is displayed and added to the ge-
	ometry. CTRL-middle clicking selects a triangle (and
	not nodes) to be deleted. Again, it may be
	easier to pick triangles with clipping planes
	on.
Flip triangle mode	Will change the order of drawing the triangle's
	points. This will cause front-facing triangles
	to become back-facing and vice-versa.
Edit node mode	Will allow you to pick a point and translate
	it with the keyboard transform controls (see
Edit landmark point mode	Section 8.2.2, keypad controls) Will allow you to pick a landmark point and
Edit fandinark point mode	translate it with the keyboard transform con-
	trols (see Section 8.2.2, keypad controls)
Delete node mode	Will remove from the geometry any node that
	you pick and any triangles associated with it.
Size of picking aperture	select the size of the region around the mouse
	pointer that will register a "hit" when picking;
	larger values will make it easier to pick an
Show Time Signal Window info	object but also easier to hit multiple objects. Toggles display modes in time series window.
Phow Time Signar Willidow Illio	When there is no info, the graph takes up
	more room in the window. This is equiva-
	lent to pressing 'p' in a geometry window or
	selecting the toggle display mode option of a
	time series window's menu.
Show all pick windows	Causes all Time Series (Pick) Windows asso-
TT-1 11 - 1 - 1	ciated with this geometry to become visible.
Hide all pick windows	Causes all Time Series (Pick) Windows asso-
	ciated with this geometry to become hidden.

Table 9: Pick mode menus. Picking is based on a mode (selectable in this menu), and is done with CTRL-left mouse button unless otherwise specified.

Node Marking Menus		
All		Make all the nodes in this (or all) surface(s)
	Sphere	mark each node with a sphere
	Node #	mark each node with the node number in the
	,,	geometry
	Channel #	mark each node with the associated data
	0	channel number
	Data value	mark each node with the associated data value
	Color	set the color for marking all nodes
	Size	set the size of all node markings
	Clear all marks	remove all node marking settings
Extrema	Cicai an marks	Make all the nodes that are the extrema
Zhu chia	Sphere	mark each extrema with a sphere
	Node #	mark each extrema with the node number in
	Trode #	the geometry
	Channel #	mark each extrema with the associated data
	Chainer #	channel number
	Data value	mark each extrema with the associated data
	Data value	
	Size	value
		set the size of all extrema markings
m: 1	Clear all marks	remove all extrema marking settings
Time signal		Make all the nodes that identify the location
	G 1	of time signals shown in the display
	Sphere	mark each times signal location with a sphere
	Node #	mark each times signal location with the node
	G1 1 //	number in the geometry

9 Output from map3d

To get output from map3d, you can output a screen shot of a Geometry window by selecting "Save..." from the Window Attributes submenu, selecting a filename in the image section, and clicking OK (see Section 8.5.2). You could, if you rather, use other means, such as SGI's snapshot utility, Windows CTRL-PrintScreen (and pasting into a paint program), or taking a picture of the screen with a camera.

10 BUGS

Too many to even begin to contemplate. But if there are any you would like exterminated, please send email to map3d@sci.utah.edu (we accept all foreign currency in large denominations, bicycle parts, assorted outdoor gear, but no credit cards).

Here is a short list of those we know about and are currently addressing:

- There is some trouble in opening .geom files saved from the Windows version of map3d.
- On X-windows-based systems, we cannot save images from screens whose default color depth is not 24 bits.
- Also on X-windows-based systems, we cannot save images when map3d is remote-displayed on a Macintosh. This will be fixed ASAP.
